Abstract

The masses and decays of the scalar $\mathrm{D}_{s0}^*(2317)$ and axial-vector $\mathrm{D}_{s1}^*(2460)$ charmed strange mesons are calculated consistently in the hadrogenesis conjecture. These mesons decay either strongly into the isospin-violating $\pi^0\mathrm{D}_s$ and $\pi^0\mathrm{D}_s^*$ channels or electromagnetically. They are generated by coupled-channel dynamics based on the leading order chiral Lagrangian. The effect of chiral corrections to chiral order Q_χ^2 is investigated. We show that taking into account large-N_c relations to determine the strength of these correction terms implies a measurable signal for an exotic axial-vector state in the $\eta\, D^*$ invariant mass distribution. The one-loop contribution to the electromagnetic decay amplitudes of scalar and axial-vector states is calculated. The Lagrangian describing electromagnetic interactions is obtained by gauging the chiral Lagrangian for hadronic interactions and adding gauge-invariant correction terms to chiral order Q_χ^2. In addition the role of light vector meson degrees of freedom is explored. We confront our results with measured branching ratios. Once the light vector mesons are included, a natural explanation of all radiative decay parameters is achieved.

1 Introduction

The observation [1,2] of two narrow, positive parity, charmed strange mesons at masses lower than expected in quark models [3,4] may provide new insight into the way hadrons are generated. The properties of these two mesons, the scalar $\mathrm{D}^*_{s0}(2317)^\pm$ and the axial-vector $\mathrm{D}^*_{s1}(2460)^\pm$, appear indeed sensitive to the degrees of freedom building up hadronic excitations and to strong interaction symmetries [5,6]. It is therefore of interest to compute the properties of these states in effective field theories involving hadronic degrees of freedom and constrained by specific symmetries.

The importance of symmetries in constructing effective actions describing heavy-light mesons was emphasized a long time ago. As early as 1993, Nowak, Rho and Zahed [7] derived an effective action combining chiral and heavy-quark symmetries and predicted that the pseudoscalar (0^-) and vector (1^-) ground states should have chiral partners as a consequence of the spontaneous breaking of chiral symmetry. The splitting between the two sets of states was found to be rather small (of the order of the constituent quark mass). It was also noted that the large N_c limit appeared compatible with the heavy-quark limit in the heavy-light meson sector. Later work by the same authors [8] addressed specifically the observed $\mathrm{D}_{s0}^*(2317)$ and $\mathrm{D}_{s1}^*(2460)$ mesons. Similar considerations linking chiral and heavy-quark symmetries to parity-doubled heavy-light mesons systems were published at the same time by Bardeen and Hill [9]. These papers rely on the chiral quark model which predicts the heavy-light 0^+ and 1^+ states as chiral partners of the heavy-light 0^- and 1^- antitriplet states. There is no prediction of that kind for non-linear realizations of the chiral SU(3) group.

The discovery of the $\mathrm{D}_{s0}^*(2317)$ and $\mathrm{D}_{s1}^*(2460)$ mesons in 2003 and the difficulty of conventional approaches to reproduce their masses motivated a large number of theoretical studies involving different descriptions based on multiquark states, molecular pictures or dynamical generation of resonances (see [5,6] for a broad set of references).

In order to get more insight into the nature of the $\mathrm{D}_{s0}^*(2317)$ and $\mathrm{D}_{s1}^*(2460)$ mesons, it was pointed out by Mehen and Springer [10] that the electromagnetic decays of these states could be most helpful in distinguishing among models. This property was illustrated by a specific comparison of leading order heavy-hadron chiral perturbation theory predictions for these decays to a corresponding calculation in the molecular picture.

The purpose of our paper is to study consistently the masses, electromagnetic and strong decays of the $\mathrm{D}_{s0}^*(2317)$ and $\mathrm{D}_{s1}^*(2460)$ mesons in the hadrogenesis conjecture where earlier work [11,12,13] showed that such states can be produced at their observed masses. This approach for heavy-light mesons exploits both heavy-quark and spontaneously broken chiral symmetries and generates D_s-mesons through relativistic coupled-channel dynamics. Goldstone bosons are scattered off heavy-light pseudoscalar and vector D-meson ground states. For the $\mathrm{D}_{s0}^*(2317)^+$ meson, the calculation involves the ηD_s^+, $K^0 D^+$ and $K^+ D^0$ channels coupled further to the $\pi^0 D_s^+$ channel through an isospin-mixing parameter. Analogously we consider for the $\mathrm{D}_{s1}^*(2460)^+$ meson the ηD_s^{*+}, $K^0 D^{*+}$, $K^+ D^{*0}$ and $\pi^0 D_s^{*+}$ channels. The strong, parity-violating decays of the $\mathrm{D}_{s0}^*(2317)$ and $\mathrm{D}_{s1}^*(2460)$ mesons give the main part of their total widths and reflect both the coupled-channel dynamics and the treatment of isospin-mixing effects. The electromagnetic widths are very sensitive to the details of the coupled-channel dynamics and to the vector degrees of freedom treated explicitly in the interaction Lagrangian.

A series of papers have addressed specific issues related to the contents of our work. The $\mathrm{D}_{s0}^*(2317)$ and $\mathrm{D}_{s1}^*(2460)$ mesons were dynamically generated based on the leading order heavy chiral Lagrangian by Guo et al. [14,15]. They also computed the strong decays of the $\mathrm{D}_{s0}^*(2317)$ and $\mathrm{D}_{s1}^*(2460)$ mesons. As this calculation is quite comparable to our first step leading order derivation, we will compare our results for the strong widths and comment on the differences. Open-charm meson systems and their decays were also studied from a Lagrangian based on the SU(4) flavour symmetry by Gamermann et al. [16,17,18]. The starting SU(4) degeneracy in this approach is quite different from the light-quark chiral symmetry and charmed quark heavy-quark symmetry underlying our work. The SU(4) symmetry is not an approximate symmetry in the presence of a heavy quark and needs to be largely broken by phenomenological interactions [16]. It is therefore expected that the properties of heavy-light mesons will differ significantly in both approaches even though specific effects in radiative decays can be similar. We will illustrate this point in the discussion of the electromagnetic decay of the $\mathrm{D}^*_{s0}(2317)$ state. The $\mathrm{D}^*_{s0}(2317)$ and $\mathrm{D}^*_{s1}(2460)$ mesons were interpreted as hadronic molecules by Faessler et al. [19,20]. It is assumed that the $\mathrm{D}^*_{s0}(2317)$ is a strong bound state of K and D mesons while the $\mathrm{D}^*_{s1}(2460)$ is treated as a bound state of K* and D mesons. The strong and radiative decays were calculated using a phenomenological Lagrangian. While this phenomenological approach is quite far from our description, we find some common features in the strong decay properties. We will point them out.

We summarize now the experimental data available on the charmed strange mesons. We display in Fig. 1 the $\mathrm{D}^\pm_s$-meson spectrum as presently known [21,22]. We also indicate the DK threshold whose closeness to the $\mathrm{D}^*_{s0}(2317)$ and $\mathrm{D}^*_{s1}(2460)$ mesons influences the dynamics of these states. The spin and parity of the $\mathrm{D}^\pm_s$-mesons are well-established for the ground state and for the $\mathrm{D}^*_{s1}(2460)^\pm$. The spin and parity of the other states need confirmation. We have quoted their most probable values.

The $\mathrm{D}^*_s(2112)^\pm$ and $\mathrm{D}^*_{s0}(2317)^\pm$ mesons lie below the DK threshold and are therefore expected to be very narrow states. They can decay either electromagnetically or into the isospin-violating $\mathrm{D}^\pm_s\,\pi^0$ channel.

The $\mathrm{D}^*_s(2112)$ has a width $\Gamma < 1.9$ MeV and decays dominantly by a radiative transition to the scalar ground state with a probability of (94.2 ± 0.7) % [21]. Its decay probability to the $D_s\pi^0$ channel is therefore (5.8 ± 0.7) %.

The most stringent upper limit obtained for the $\mathrm{D}^*_{s0}(2317)$ width is $\Gamma <$ 3.8 MeV [23]. The $\mathrm{D}^*_{s0}(2317)$ was first observed through its decay into the $\mathrm{D}_s(1968)\,\pi^0$ channel [1]. Its radiative decay to the $\mathrm{D}_s(1968)$ has never been seen. The upper limits available on the ratio of the radiative to pionic decay widths of the $\mathrm{D}^*_{s0}(2317)$ to the ground state and to the $\mathrm{D}^*_s(2112)$ are [21]

$$\frac{\Gamma\,[D^*_{s0}(2317)\,\rightarrow\,D_s(1968)\,\gamma]}{\Gamma\,[D^*_{s0}(2317)\,\rightarrow\,D_s(1968)\,\pi^0]} < 0.05 \qquad (1)$$

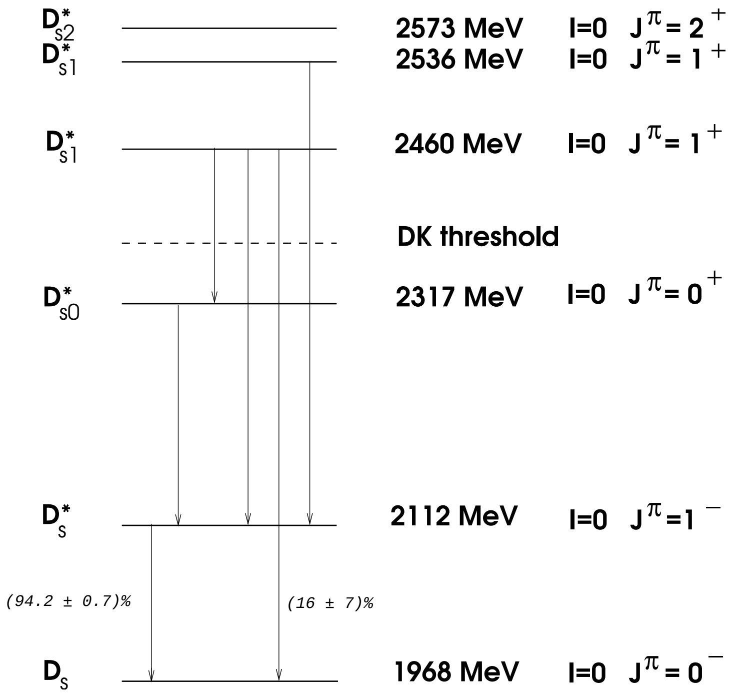

Fig. 1. The $D_s^\pm$-meson spectrum with the most probable spin-parity assignments together with the radiative transitions on which there is experimental information [21,22]. The arrows without number indicate that there are experimental constraints on these decays but no absolute branching ratios. The dashed line shows the DK threshold.

$$\frac{\Gamma\left[D^*_{s0}(2317)\;\rightarrow\;D^*_s(2112)\,\gamma\right]}{\Gamma\left[D^*_{s0}(2317)\;\rightarrow\;D_s(1968)\,\pi^0\right]} < \;0.059. \tag{2}$$

The $D^*_{s1}(2460)$ meson is located above the DK threshold but appears nevertheless very narrow: its total width was found to be less than 3.5 MeV [23]. Constraints on its radiative decays to the $D_s(1968)$, to the $D^*_s(2112)$ and to the $D^*_{s0}(2317)$ are as follows [21],

$$\frac{\Gamma\left[D^*_{s1}(2460)\;\rightarrow\;D_s(1968)\,\gamma\right]}{\Gamma\left[D^*_{s1}(2460)\;\rightarrow\;D^*_s(2112)\,\pi^0\right]} = 0.31 \pm 0.06, \tag{3}$$

$$\frac{\Gamma\left[D^*_{s1}(2460)\;\rightarrow\;D^*_s(2112)\,\gamma\right]}{\Gamma\left[D^*_{s1}(2460)\;\rightarrow\;D^*_s(2112)\,\pi^0\right]} < \;0.16, \tag{4}$$

$$\frac{\Gamma\left[D^*_{s1}(2460)\;\rightarrow\;D^*_{s0}(2317)\,\gamma\right]}{\Gamma\left[D^*_{s1}(2460)\;\rightarrow\;D^*_s(2112)\,\pi^0\right]} < \;0.22. \tag{5}$$

An absolute measurement of the decay probability of the $\mathrm{D}_{s1}^{*}(2460)^{-}$ to the $D_s(1968)^{-}\,\gamma$ channel gave recently $(16 \pm 7)\%$ [22]. The same data also provided the branching fraction $\mathrm{B}(D_{s1}^{*}(2460)^{-} \rightarrow D_{s}^{*}(2112)^{-}\pi^{0}) = (56 \pm 22)\%$. The ratio is in agreement with the value quoted in (3).

The $\mathrm{D}_{s1}^{*}(2536)$ and $\mathrm{D}_{s2}^{*}(2573)$ widths were recently measured to be $(1.03{\pm}0.017)$ MeV and $(27.1\ {\pm}6.2)$ MeV respectively [24,25]. The radiative decay widths of these states are not known.

We restrict our calculations to the radiative and isospin-violating π^0 decays of the $\mathrm{D}_{s0}^{*}(2317)^{+}$ and $\mathrm{D}_{s1}^{*}(2460)^{+}$ states on which there are fragmentary but significant data. We note that the presence of a 2^+ state about 100 MeV above the $\mathrm{D}_{s1}^{*}(2460)^{+}$ state is an indication of physics outside our scheme around that energy scale which should guide future investigations of higher-lying states. In view of the uncertainties in the measured widths of the D_{s0}^{*} and D_{s1}^{*} states, our main concern will be to check the ability of the hadrogenesis conjecture to provide a consistent picture of the main features of the decay scheme. We aim at identifying the important contributions to the dynamics of these decays, determining characteristic ranges for the parameters involved and making predictions able to test further the structure of the D_s-mesons and the specific conjecture on which this work relies.

This paper is organized as follows. Section 2 is devoted to the generation of the $\mathrm{D}_{s0}^{*}(2317)^{+}$ and $\mathrm{D}_{s1}^{*}(2460)^{+}$ mesons and to the calculation of their strong isospin-violating decay widths. We present first a calculation based on the leading order chiral Lagrangian in which massive vector particles are described in terms of antisymmetric tensor fields. We introduce subsequently chiral correction terms to chiral order Q_{χ}^{2} to take into account s- and u-channel D-meson exchange processes and local two-body counter terms. Section 3 deals with the coupling of the electromagnetic field to the hadrons. In a first step we gauge the hadronic interactions introduced in Section 2. We add gauge-invariant interaction terms of chiral order Q_{χ}^{2}. We consider also interaction vertices probed when including the light vector mesons as explicit degrees of freedom. We comment on the values of the parameters associated with these terms in relation to QCD symmetries and discuss the renormalization of the ultraviolet singularities. The explicit expressions of the electromagnetic decays are derived in Section 4 for the scalar state $\mathrm{D}_{s0}^{*}(2317)$ and in Section 5 for the axial-vector state $\mathrm{D}_{s1}^{*}(2460)$. Our numerical results are presented in Section 6 and compared to the available data. We discuss the role of the different contributions and the constraints expected on the range of values for the coupling constants of specific interaction terms. We conclude in Section 7. We relegate lengthy derivations in seven appendices (A-G).

2 Generation and strong isospin-violating decays of molecules

This section deals with the generation of the scalar $D_{s0}^*(2317)$ and isovector $D_{s1}^*(2460)$ mesons in the coupled-channel framework of [12,13]. This description is based on the scattering of Goldstone bosons off heavy-light 0^- and 1^- mesons respectively. Isospin-breaking effects arise from the difference between the up and down quark masses which leads to isospin-violating strong decay amplitudes, $D_{s0}^*(2317) \to \pi^0\, D_s$ and $D_{s1}^*(2460) \to \pi^0\, D_s^*$. These isospin-breaking effects were not included in earlier work based on the assumption of perfect isospin symmetry [12,13]. We consider scalar and axial-vector states successively. In the latter case, we reformulate the derivation of [12,13] in terms of massive 1^- fields represented by antisymmetric tensors. This particular development is needed later to arrive at expressions which are gauge-invariant in a transparent manner. For both states, we consider first the hadronic interactions resulting from the leading order chiral Lagrangian and treat afterwards chiral corrections to chiral order Q_χ^2.

We emphasize the importance of studying scalar and axial-vector mesons in the open-charm sector on equal footing. The properties of spin 0 and spin 1 heavy-light mesons are indeed closely related by the heavy-quark symmetry of QCD [26,27,28,29,30]. Even though the charm quark mass is much larger that the light (u,d,s) quark masses, the limit in which the mass of the charm quark goes to infinity is an approximation which may require significant corrections [31,32]. Rather than applying a formalism where scalar and vector fields are fully degenerate and grouped together in one field as implied by exact heavy-quark symmetry, we use separate scalar and vector D-meson fields to allow for the observed mass difference between spin multiplets.

2.1 The scalar state $D_{s0}^*(2317)$

The open-charm $D_{s0}^*(2317)$ state has been shown to be dynamically generated as a direct consequence of the leading order chiral Lagrangian density [12,13],

$$\begin{aligned}\mathcal{L} = &\frac{1}{4}\,\mathrm{tr}\,(\partial_\mu \Phi)\,(\partial^\mu \Phi) - \frac{1}{4}\,\mathrm{tr}\,\chi_0\,\Phi^2 + \;(\partial_\mu \mathrm{D})\,(\partial^\mu \bar{\mathrm{D}}) - \mathrm{D}\,\mathrm{M}_{0^-}^2\,\bar{\mathrm{D}} \\ &+ \frac{1}{8\,f^2}\left\{(\partial^\mu D)\;[\Phi,(\partial_\mu\Phi)]_-\,\bar{D} - D\;[\Phi,(\partial_\mu\Phi)]_-\,(\partial^\mu\bar{D})\right\}, \qquad (6)\end{aligned}$$

where Φ and D are the pseudoscalar octet and triplet fields. We use the notation $\bar{D} = D^\dagger$. In the particle representation the Goldstone and ground state open-charm meson fields are

$$\Phi = \begin{pmatrix} \pi^0 + \frac{1}{\sqrt{3}}\,\eta & \sqrt{2}\,\pi^+ & \sqrt{2}\,K^+ \\ \sqrt{2}\,\pi^- & -\pi^0 + \frac{1}{\sqrt{3}}\,\eta & \sqrt{2}\,K^0 \\ \sqrt{2}\,K^- & \sqrt{2}\,\bar{K}^0 & -\frac{2}{\sqrt{3}}\,\eta \end{pmatrix} \,, \qquad D = (D^0, -D^+, D_s^+)\,. \tag{7}$$

The Weinberg-Tomozawa term in (6), which is proportional to f^{-2}, is obtained by chirally gauging the kinetic term of the D-mesons. It is of chiral order Q_χ as it involves a single derivative of the light Goldstone fields. The parameter $f \simeq f_\pi = 92.4$ MeV in (6) is the octet meson decay constant. It defines the scale of chiral symmetry breaking and is approximatively known from the weak decay of the charged pions. A precise determination of f requires a chiral SU(3) extrapolation of some data set. In [33] the value $f \simeq 90$ MeV was obtained from a detailed study of pion- and kaon-nucleon scattering data. We will use $f = 90$ MeV throughout this work unless specified otherwise. This parameter determines the leading s-wave interaction of the Goldstone bosons with the open-charm meson fields. We note that our approach is consistent with heavy-hadron chiral perturbation theory [10] but at variance with the work of [16,17,18] where the large breaking of the assumed SU(4) flavour symmetry leads to different interactions. The ground state scalar D-meson mass matrix is denoted by M_{0^-}. The mass term of the Goldstone bosons is proportional to the quark-mass matrix

$$\chi_0 = 2\,B_0 \begin{pmatrix} m_u & 0 & 0 \\ 0 & m_d & 0 \\ 0 & 0 & m_s \end{pmatrix} = \frac{1}{3}\left(m_\pi^2 + 2\,m_K^2\right)\,1 + \frac{2}{\sqrt{3}}\,\left(m_\pi^2 - m_K^2\right)\lambda_8\,. \tag{8}$$

At leading order the latter can be expressed in terms of the pion and kaon masses as indicated in (8).

If we admit isospin-breaking effects, i.e. $m_u \neq m_d$, there is a term in (6) proportional to $(m_u - m_d)\,\pi^0\,\eta$, inducing $\pi^0\,\eta$ mixing. A unitary transformation is required such that the transformed fields $\tilde{\pi}^0$ and $\tilde{\eta}$ defined by

$$\pi^0 = \tilde{\pi}^0\,\cos\epsilon - \tilde{\eta}\,\sin\epsilon\,, \qquad \eta = \tilde{\pi}^0\,\sin\epsilon + \tilde{\eta}\,\cos\,\epsilon\,, \tag{9}$$

decouple. The Lagrangian density (6), when written in terms of the new fields, does not show a $\tilde{\pi}^0\,\tilde{\eta}$ term if and only if

$$\frac{\sin(2\,\epsilon)}{\cos(2\,\epsilon)} = \sqrt{3}\,\frac{m_d - m_u}{2\,m_s - m_u - m_d}\,. \tag{10}$$

According to [34] the ratio of quark masses relevant in (10) takes the value

$$\frac{m_d - m_u}{m_s - (m_u + m_d)/2} = \frac{1}{43.7 \pm 2.7}\,, \tag{11}$$

which implies the mixing angle

$$\epsilon = 0.010 \pm 0.001\,. \tag{12}$$

Heavy-light meson resonances with quantum numbers $J^P = 0^+$ manifest themselves as poles in the s-wave scattering amplitude $T(s)$. We consider the four isospin states $\langle K\,D, I|$, $\langle \pi\,D_s, 1|$ and $\langle \eta\,D_s, 0|$. In the presence of isospin mixing all channels couple. The mixing of the two isospin sectors is of order ϵ. Using the phase convention of [12,13], we define the four states

$$\begin{aligned}
\langle 1| &= \langle\, \tilde{\pi}^0\, D_s^+| = \cos\epsilon\,\langle \pi^0\,D_s, 1| + \sin\epsilon\,\langle \eta\,D_s, 0|\,,\\
\langle 2| &= \langle\, \tilde{\eta}\;\; D_s^+| = \cos\epsilon\,\langle \eta\,D_s, 0| - \sin\epsilon\,\langle \pi^0\,D_s, 1|\,,\\
\langle 3| &= \langle K^0 D^+| = +\tfrac{1}{\sqrt{2}}\,(\langle K\,D, 0| - \langle K\,D, 1|)\,,\\
\langle 4| &= \langle K^+ D^0| = -\tfrac{1}{\sqrt{2}}\,(\langle K\,D, 0| + \langle K\,D, 1|)\,.
\end{aligned} \tag{13}$$

The Weinberg-Tomozawa interaction (6) implies a scattering amplitude of the simple form [12,13]

$$T(s) = \Big[1 - V(s)\,J(s)\Big]^{-1}\,V(s)\,. \tag{14}$$

The matrix of loop functions, $J(s)$, is diagonal and given by [12,13]

$$\begin{aligned}
J(s) &= I(s) - I(\mu_M^2)\,,\\
I(s) &= \frac{1}{16\,\pi^2}\left(\frac{p_{cm}}{\sqrt{s}}\left(\ln\left(1 - \frac{s - 2\,p_{cm}\sqrt{s}}{m^2 + M^2}\right) - \ln\left(1 - \frac{s + 2\,p_{cm}\sqrt{s}}{m^2 + M^2}\right)\right)\right.\\
&\qquad \left. + \left(\frac{1}{2}\,\frac{m^2 + M^2}{m^2 - M^2} - \frac{m^2 - M^2}{2\,s}\right)\ln\left(\frac{m^2}{M^2}\right) + 1\right) + I(0)\,,
\end{aligned} \tag{15}$$

where $\sqrt{s} = \sqrt{M^2 + p_{cm}^2} + \sqrt{m^2 + p_{cm}^2}$ and p_{cm} is the center of mass momentum of the scattering particles. Each diagonal element depends on the masses of the light (Goldstone) and heavy (open-charm) mesons m and M defining the coupled-channel state. The matching scale μ_M in (15) should be identified with the ground state mass of the D_s-meson, i.e. $\mu_M \simeq 1968$ MeV [33]. For such a value, s- and u-channel unitarized scattering amplitudes may be smoothly matched around the matching scale so as to define a full scattering amplitude that is crossing symmetric by construction. The determination of the matching scale and the induced approximate crossing symmetry parallels the derivation published for kaon-nucleon scattering in [33]. The minimal critical point needed to open the matching window for πD_s or KD scattering is typically of the order of $\sqrt{m_\pi^2 + M_{D_s}^2} \simeq \sqrt{m_K{}^2 + M_D^2} \simeq M_{D_s}$. One may vary the matching scale slightly around its natural value. As shown in [11] the resulting effects are small for reasonable variations. A large variation is excluded since it would make the matching of u- and s-channel unitarized amplitudes possible only at the price of introducing a strong discontinuity, which is at odds with causality.

The coupled-channel interaction kernel $V_{ij}(s)$ in (14) is determined by the leading order chiral SU(3) Lagrangian (6) to be [12],

$$\begin{aligned} V^{(0^+)}_{WT,ij}(s) &= \frac{C_{ij}}{8\,f^2} \\ &\times \Big(3\,s - M^2 - \bar{M}^2 - m^2 - \bar{m}^2 - \frac{M^2-m^2}{s}\,(\bar{M}^2-\bar{m}^2)\Big)\,, \end{aligned} \tag{16}$$

where (m, M) and $(\bar{m}, \bar{M})$ are the masses of initial and final mesons and the indices i and j refer to the states defined in (13). The 4×4 matrix C_{ij}, whose elements characterize the interaction strength in a given channel, can be expressed in terms of the mixing angle ϵ and the isospin zero $C^{(0)}_{ij}$ and isospin one $C^{(1)}_{ij}$ coupling matrices of [12]. For the channels of positive strangeness considered in (13), we have

$$\begin{aligned}
&C_{11} = C^{(0)}_{22}\,\sin^2\epsilon + C^{(1)}_{11}\,\cos^2\epsilon && C_{12} = (C^{(0)}_{22} - C^{(1)}_{11})\,\sin\epsilon\,\cos\epsilon \\
&C_{22} = C^{(0)}_{22}\,\cos^2\epsilon + C^{(1)}_{11}\,\sin^2\epsilon && C_{13} = \tfrac{1}{\sqrt{2}}\Big(C^{(0)}_{12}\,\sin\epsilon - \cos\epsilon\,C^{(1)}_{12}\Big) \\
&C_{23} = \tfrac{1}{\sqrt{2}}\Big(\cos\epsilon\,C^{(0)}_{12} + \sin\epsilon\,C^{(1)}_{12}\Big) && C_{33} = \tfrac{1}{2}\Big(C^{(0)}_{11} + C^{(1)}_{22}\Big) \\
&C_{14} = \tfrac{-1}{\sqrt{2}}\Big(C^{(0)}_{12}\,\sin\epsilon + C^{(1)}_{12}\,\cos\epsilon\Big) && C_{24} = \tfrac{-1}{\sqrt{2}}\Big(C^{(0)}_{12}\,\cos\epsilon - C^{(1)}_{12}\,\sin\epsilon\Big) \\
&C_{34} = \tfrac{-1}{2}\Big(C^{(0)}_{11} - C^{(1)}_{22}\Big) && C_{44} = \tfrac{1}{2}\Big(C^{(0)}_{11} + C^{(1)}_{22}\Big) \\
&C^{(0)}_{11} = 2 = 2\,C^{(1)}_{12} \qquad C^{(0)}_{12} = \sqrt{3} && C^{(0)}_{22} = C^{(1)}_{11} = C^{(1)}_{22} = 0\,.
\end{aligned} \tag{17}$$

Given the coupled-channel scattering amplitude (14) with the effective interaction (16), it is straightforward to determine the mass and width of possible resonances. The Weinberg-Tomozawa interaction is strongly attractive in the isospin strangeness (I,S) = (0,1) sector, leading to the formation of a scalar resonance of mass M_{0^+}. The latter manifests itself as a pole in the scattering amplitude which factorizes close to the pole at $s = M^2_{0^+}$,

$$T_{ij}(s) \simeq -\frac{2\,g_i^*\,M^2_{0^+}g_j}{s - M^2_{0^+} + i\,\Gamma_{0^+}\,M_{0^+}}\,, \tag{18}$$

with the coupling constants g_i and the width Γ_{0^+}. We do not consider the possibility of background terms as we are dealing with a narrow resonance.

The numerical results obtained at leading order should be viewed as qualitative. At the end of this section more quantitative results including chiral corrections will be presented.

To reproduce the empirical mass of 2317.6 MeV at leading order for the 0^+ state requires using an effective parameter $f_{eff} = 95.5$ MeV in (16). Taking $\epsilon = 0.010$, the coupling constants are

$$\begin{aligned} &g_{\eta\, D_s} \simeq 1.95\,, && g_{\pi^0 D_s} \simeq 0.056, \\ &g_{K^0 D^+} \simeq 2.25\,, && g_{K^+ D^0} \simeq -2.25\,. \end{aligned} \tag{19}$$

Isospin-breaking effects in the KD coupling constants are found to be negligible, i.e. $g_{K^0 D^+} \simeq -g_{K^+ D^0}$ holds quite accurately. It is therefore meaningful to work with the isospin coupling constants

$$g^{(0+)}_{KD} = \sqrt{2}\, g_{K^0 D^+} \simeq 3.18\,, \qquad g^{(0+)}_{\eta\, D_s} = g_{\eta\, D_s} \simeq 1.95\,. \tag{20}$$

The flavour SU(3) limit suggests $\sqrt{3}\, g^{(0+)}_{\eta D_s} = g^{(0+)}_{KD}$, a result quite compatible with the values given in (19, 20).

The strong width of the $D^*_{s0}(2317)$ is related to $g_{\pi^0 D_s}$ by

$$\Gamma_{D^*_{s0}(2317)\to \pi^0 D_s} = |g_{\pi^0 D_s}|^2\, \frac{p_{cm}}{4\,\pi} \simeq |g_{\pi^0 D_s}|^2\, 23.7\,\mathrm{MeV} \simeq 76\,\mathrm{keV}\,, \tag{21}$$

where p_{cm} is the pion momentum in the center of mass frame. Our value of 76 keV is almost an order of magnitude larger than the value given in [14] based on the same interaction.

To trace the origin of this difference, it is useful to understand the physics underlying $g_{\pi^0 D_s}$. At linear order in isospin breaking, it is the sum of two terms,

$$g_{\pi^0 D_s} = \tilde{\epsilon}\, g^{(0+)}_{KD} + \epsilon\, g^{(0+)}_{\eta D_s}\,. \tag{22}$$

The contribution proportional to $g^{(0+)}_{\eta D_s}$ is unambiguously determined by the angle ϵ, as a direct consequence of the $\pi^0\eta$ mixing defined in (9), and linked to the finite value of $(m_u - m_d)$. If it were the only contribution to $g_{\pi^0 D_s}$, the corresponding strong width $\Gamma_{D^*_{s0}(2317)\to \pi^0 D_s}$ would be $\sim$ 9 keV, a value compatible with the 8.7 keV obtained in [14] based on $\pi^0\eta$ mixing.

The contribution proportional to $g_{KD}^{(0+)}$ appears at the same level and is not included in [14]. It is induced by the mass difference between the neutral and charged kaons and between the neutral and charged D-mesons. Like the $\pi^0\eta$ mixing phenomenon, it couples the two isospin sectors and is related to the finite value of $(m_u - m_d)$. It is clearly not there if one assumes $m_{K^+} = m_{K^0}$ and $M_{D^+} = M_{D^0}$. This effect in chiral coupled-channel dynamics is analogous to the mixing phenomenon recently pointed out in the molecular picture [19,20] where it is induced by the exchange of vector K*- and D*-mesons. The parameter $\tilde{\epsilon}$ in (22) must have the form

$$\tilde{\epsilon} = \tilde{\epsilon}_1 + \tilde{\epsilon}_2 \,, \qquad \tilde{\epsilon}_1 \sim (m_{K^+} - m_{K^0}) \,, \qquad \tilde{\epsilon}_2 \sim (M_{D^+} - M_{D^0}) \,, \tag{23}$$

where the proportionality factors depend on the details of the coupled-channel dynamics. At leading order we predict $\tilde{\epsilon} \simeq 0.012$ with $\tilde{\epsilon}_1 \simeq 0.004$ and $\tilde{\epsilon}_2 \simeq 0.008$. The term $\tilde{\epsilon}\, g_{KD}^{(0+)}$ in $g_{\pi^0 D_s}$ is roughly twice larger than $\epsilon\, g_{\eta D_s}^{(0+)}$ and appears dominated by the isospin-breaking induced by $M_{D^+} \neq M_{D^0}$. These results agree qualitatively with the findings of [19,20].

We mention two sources of uncertainty in the value derived above for the strong width of the $D_{s0}^*(2317)$. First we use the physical masses of the neutral and charged kaons and D-meson including the electromagnetic contribution to these masses. The latter should in principle be generated by the coupling of the hadronic Lagrangian to the electromagnetic field. The splitting of hadronic and electromagnetic interactions is a nontrivial issue [35,36] which we do not address here. The use of physical masses in the unitarization loop function (15) is in line with the scheme developed in [33]. Loop corrections implied by photon-exchange processes enter the effective coupled-channel interaction $V(s)$ in (14) at order Q_χ^3. Another source of uncertainty lies in the coupling constants $g_{\eta D_s}$ and g_{KD}. It was shown in [13] that chiral correction terms of order Q_χ^2 modify these couplings and lead to the values $g_{\eta D_s} \simeq 3.7$ and $g_{KD} \simeq 3.7$. The width of 76 keV quoted above is therefore most likely a lower limit as suggested by inserting the coupling constants of [13] into (21) and (22). We will return to this issue in the final part of this section.

2.2 The axial-vector state $D_{s1}^*(2460)$

We turn to the generation and strong decay of the axial-vector meson $D_{s1}^*(2460)$. This calculation involves the same procedure as followed for the scalar state except that we now build the axial-vector state by scattering Goldstone bosons off vector D-mesons.

Since we aim at predicting electromagnetic decay amplitudes, we have to construct gauge-invariant expressions. Our Lagrangian involves massive scalar and vector D-meson particles. We are faced with a serious complication, namely, the mixing of scalar and vector modes. It is a quite cumbersome enterprize to arrive at gauge-invariant expressions in the presence of such mixing phenomena [37,38,39]. This is a known and non-trivial complication of the standard model where the Higgs boson may mix with the longitudinal component of the Z boson [40]. A solution to this problem is to represent the 1^- D-mesons in terms of antisymmetric tensor fields [41,42,43,44]. The massive vector field is proportional to the divergence of the antisymmetric tensor.

To proceed with this particular representation we demonstrate first that the results of [12], which were obtained using the conventional vector field representation, can be recovered with the tensor field representation.

We start with the Lagrangian density,

$$\begin{aligned} \mathcal{L} = &-(\partial_\mu D^{\mu\alpha})\,(\partial^\nu \bar{D}_{\nu\alpha}) + \frac{1}{2}\,D^{\mu\alpha}\,M^2_{1^-}\,\bar{D}_{\mu\alpha} \\ &-\frac{1}{8\,f^2}\Big\{(\partial^\nu D_{\nu\alpha})\;[\Phi,(\partial_\mu\Phi)]_-\;\bar{D}^{\mu\alpha} - D_{\nu\alpha}\;[\Phi,(\partial_\nu\Phi)]_-\;(\partial_\mu\bar{D}^{\mu\alpha})\Big\}\,, \end{aligned} \tag{24}$$

involving the kinetic term and its associated Weinberg-Tomozawa interaction. The antisymmetric triplet fields $D_{\mu\nu} = -D_{\nu\mu}$ and $\bar{D}_{\mu\nu} = D^\dagger_{\mu\nu}$ with $D_{\mu\nu} = (D^0_{\mu\nu}, -D^+_{\mu\nu}, D^+_{s,\mu\nu})$ describe the heavy-quark multiplet partners of the fields D introduced in (7). M_{1^-} denotes their mass matrix. Since the tensor field representation is not frequently used in the literature, we recall the definitions of the propagator and of the associated wave function,

$$\begin{aligned} \langle 0|\,T\,\bar{D}_{\mu\nu}(x)\,D_{\alpha\beta}(y)\,|0\rangle = &-\frac{i}{M^2_{1^-}}\int\frac{d^4k}{(2\pi)^4}\,\frac{e^{-i\,k\cdot(x-y)}}{k^2-M^2_{1^-}+i\,\epsilon} \\ &\times\Big[(M^2_{1^-}-k^2)\,g_{\mu\alpha}\,g_{\nu\beta}+g_{\mu\alpha}\,k_\nu\,k_\beta-g_{\mu\beta}\,k_\nu\,k_\alpha-(\mu\leftrightarrow\nu)\Big] \end{aligned} \tag{25}$$

and

$$\begin{aligned} &\langle 0|D_{\mu\nu}(0)\,|D(p,\lambda)\rangle = \epsilon_{\mu\nu}(p,\lambda) = \frac{i}{M_{1^-}}\Big[p_\mu\,\epsilon_\nu(p,\lambda)-p_\nu\,\epsilon_\mu(p,\lambda)\Big]\,, \\ &\sum_{\lambda=1}^{3}\epsilon^\dagger_\mu(p,\lambda)\,\epsilon_\nu(p,\lambda) = -g_{\mu\nu}+\frac{p_\mu\,p_\nu}{M^2_{1^-}}\,, \end{aligned} \tag{26}$$

where the wave function is expressed most economically in terms of the conventional wave function $\epsilon_\mu(p,\lambda)$ of a vector particle in the vector representation.

To derive the on-shell scattering amplitude based on the interaction (24), we have to reformulate with the tensor representation the technique developed in

[11] using the vector representation of spin one fields. The on-shell part of the scattering amplitude in the vector representation takes the simple form,

$$T_{\mu\nu}^{\rm on-shell} = \sum_{J,P} M^{(JP)}(s)\, \mathcal{Y}_{\mu\nu}^{(JP)}(\bar{q}, q; w)\,, \tag{27}$$

where the projectors $\mathcal{Y}_{\mu\nu}^{(JP)}(\bar{q}, q; w)$ are constructed to carry well-defined total angular momentum J and parity P. The projectors are polynomials in the initial and final 4-momenta of the Goldstone bosons, q_μ and $\bar{q}_\mu$, as well as in the total 4-momentum w_μ ($w^2 = s$). We are interested only in the $J^P = 1^+$ sector to generate the $D_{s1}^*(2460)$. We recall the appropriate projector

$$\mathcal{Y}_{\mu\nu}^{(1+)} = \frac{3}{2}\Big(\frac{w^\mu\, w^\nu}{w^2} - g^{\mu\nu}\Big)\,. \tag{28}$$

The merit of the projectors is their property of solving the Bethe-Salpeter coupled-channel equation analytically for quasi-local interactions. The partial-wave amplitudes $M^{(JP)}(s)$ are Lorentz invariant. They can be computed in terms of an effective interaction $V^{(JP)}(s)$ and loop functions $J^{(JP)}(s)$,

$$\begin{aligned} &M^{(JP)}(s) = \Big[1 - V^{(JP)}(s)\, J^{(JP)}(s)\Big]^{-1} V^{(JP)}(s)\,, \\ &J^{(JP)}(s) = N^{(JP)}(s)\, \Big\{ I(s) - I(\mu_M^2)\Big\}\,, \end{aligned} \tag{29}$$

where the factors $N^{(JP)}(s)$ reflect the presence of spin and angular momentum. The latter, if multiplied by an appropriate factor s^n, are polynomials in s and the masses of the intermediate states. The universal integral $I(s)$ is defined in (15). The matching scale μ_M is taken to be the mass of the vector-meson ground state, $\mu_M = 2012$ MeV, following the same reasoning as given in Section 2.1. for the scalar case.

We seek a set of tensor projectors, $\mathcal{Y}_{\mu\nu,\alpha\beta}^{(JP)}(\bar{q}, q; w)$, with properties analogous to those of $\mathcal{Y}_{\mu\nu}^{(JP)}(\bar{q}, q; w)$. They are defined in terms of the previous ones by

$$\begin{aligned} \mathcal{Y}_{\mu\nu,\alpha\beta}^{(JP)}(\bar{q}, q; w) &= \tfrac{1}{4}\, \bar{p}_\nu\, \mathcal{Y}_{\mu\alpha}^{(JP)}(\bar{q}, q; w)\, p_\beta - \tfrac{1}{4}\, \bar{p}_\nu\, \mathcal{Y}_{\mu\beta}^{(JP)}(\bar{q}, q; w)\, p_\alpha \\ &\quad - \tfrac{1}{4}\, \bar{p}_\mu\, \mathcal{Y}_{\nu\alpha}^{(JP)}(\bar{q}, q; w)\, p_\beta + \tfrac{1}{4}\, \bar{p}_\mu\, \mathcal{Y}_{\nu\beta}^{(JP)}(\bar{q}, q; w)\, p_\alpha\,, \end{aligned} \tag{30}$$

where $p_\mu = w_\mu - q_\mu$ and $\bar{p}_\mu = w_\mu - \bar{q}_\mu$. By construction we have

$$\epsilon^{\dagger,\mu\nu}(\bar{p})\, \mathcal{Y}_{\mu\nu,\alpha\beta}^{(JP)}(\bar{q}, q; w)\, \epsilon^{\alpha\beta}(p) = \sqrt{\bar{p}^2\, p^2}\, \epsilon^{\dagger,\mu}(\bar{p})\, \mathcal{Y}_{\mu\nu}^{(JP)}(\bar{q}, q; w)\, \epsilon^\nu(p)\,, \tag{31}$$

where we made use of (26). The identity (31) provides the relation we are after for the scattering amplitude,

$$T^{\rm on-shell}_{\mu\nu,\alpha\beta} = \sum_{J,P} M^{(JP)}(s)\,\mathcal{Y}^{(JP)}_{\mu\nu,\alpha\beta}(\bar q, q; w)\,, \tag{32}$$

where the invariant partial-wave amplitudes are given by an equation of the form (29). The only modification compared to the expressions of [11] is a rescaling of the loop functions by a factor M^2. The normalization factor reads

$$N^{(1+)}(s) = \frac{3}{2}\,M^2 + \frac{p_{cm}^2}{2}\,, \qquad \sqrt{s} = \sqrt{M^2+p^2_{cm}} + \sqrt{m^2+p^2_{cm}}\,. \tag{33}$$

Using a convention for the coupled-channel states analogous to (13), the effective interaction $V^{(1+)}_{ij}(s)$ implied by (24) is obtained by a straightforward application of [11],

$$V^{(1+)}_{WT,ij}(s) = \frac{\bar M^2 + M^2}{3\,\bar M^2\,M^2}\,V^{(0^+)}_{WT,ij}(s) + \frac{(\bar M^2 - M^2)}{12\,f^2\,\bar M^2\,M^2}\,(\bar m^2 - m^2)\,C_{ij}\,, \tag{34}$$

in terms of the matrix $V^{(0^+)}_{WT,ij}(s)$ and the C_{ij} coefficients defined in (17). The parameters M, $\bar M$, m and $\bar m$ have the same meaning as in (16).

In the limit $\bar M = M$, we recover the expressions obtained in [12]. The invariant amplitude $M^{(1+)}(s)$ is identical to that of [12] within a factor $2\,M^2/3$. This implies in particular that the predictions for the axial-vector spectrum are consistent with the expectation of the heavy-quark symmetry.

The $D^*_{s1}(2460)$ state is generated dynamically from the interaction Lagrangian (24). The scattering amplitude develops a pole at $s = M^2_{1^+}$. Close to the pole it has the form

$$M^{(1+)}_{ij}(s) \simeq -\frac{2}{3\,\bar M\,M}\,\frac{2\,g_i^*\,M^2_{1^+} g_j}{s - M^2_{1^+} + i\,\Gamma_{1^+}\,M_{1^+}}\,, \tag{35}$$

with the coupling constants g_i and the width parameter Γ_{1^+}. For the same reason as in (18), we do not consider background terms. The normalization of the coupling constants, g_i, is such that in the heavy-quark limit they are identical to those of (18). The values discussed in the following can be compared directly to those given in [13].

To reproduce the empirical mass of 2459 MeV at leading order for the 1^+ state requires using an effective parameter $f_{eff} = 97.2$ MeV. The coupling constants are then

$$g_{\eta\,D_s^*} \simeq 1.95\,, \qquad g_{\pi^0 D_s^*} \simeq 0.049\,,$$

$$g_{K^0 D^*_+} \simeq 2.25\,, \qquad\qquad g_{K^+ D^*_0} \simeq -2.25\,. \tag{36}$$

Isospin-breaking effects in the coupling constants are again found negligible. For a quantitative study that considers chiral correction terms we refer to the end of this section. The values (36) are identical (or very similar for $g^{(1+)}_{\pi^0 D^*_s}$) to those given in (19). This approximate degeneracy is expected from heavy-quark symmetry. The strong width of the $D^*_{s1}(2460)$ is determined by $g_{\pi^0 D^*_s}$. We get 55 keV using $\epsilon = 0.010$. Our result for the width parameter is five times larger than the value obtained in [15] based on the same interaction. The reason for such a discrepancy is again the neglect of isospin-breaking effects in the kaon and D*-meson masses in [15]. The uncertainties in the strong width discussed for the $D^*_{s0}(2317)$ apply equally for the $D^*_{s1}(2460)$.

2.3 Chiral correction terms

It was shown in [13] that chiral correction terms at subleading order (Q^2_χ) provide additional mass shifts for the D^*_{s0} and D^*_{s1} states, such that their masses are consistent with the observed values when using $f = 90$ MeV rather than the effective decay parameters f_{eff} of the previous sections. We construct these chiral corrections to the leading order interactions (6) and (24) by adjusting the expressions of [13] to the tensor representation of massive vector particles. There will be two types of contributions for s-wave scattering. On the one hand we include s- and u-channel exchanges of the D-meson ground states based on the leading order vertices involving a Goldstone boson and two D-mesons. On the other hand local 2-body counter terms (breaking chiral symmetry and chiral symmetric respectively) will be constructed. These different contributions are shown in Fig. 2.

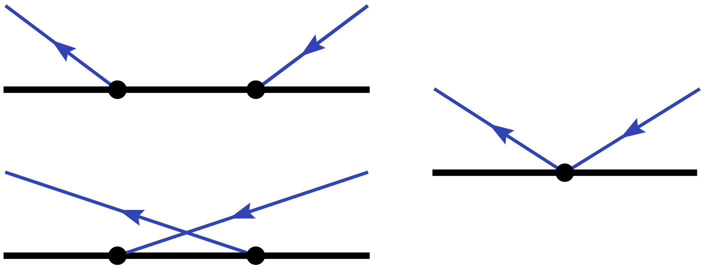

Fig. 2. Chiral correction terms from s- and u-channel exchange processes of the D-meson (left) and local 2-body counter terms (right). The thin and thick lines represent Goldstone and heavy-light mesons respectively.

The s- and u-channel exchanges of the D-meson ground states at chiral order Q^2_χ are generated by leading order (Q_χ) 3-point vertices,

$$\mathcal{L} = i\,\frac{g_P}{f}\,\Big\{ D_{\mu\nu}\,(\partial^\mu \Phi)\,(\partial^\nu \bar D) - (\partial^\nu D)\,(\partial^\mu \Phi)\,\bar D_{\mu\nu} \Big\}$$
$$+\,\frac{\tilde g_P}{4\,f}\,\epsilon^{\mu\nu\alpha\beta}\,\Big\{ D_{\mu\nu}\,(\partial_\alpha \Phi)\,(\partial^\tau \bar D_{\tau\beta}) + (\partial^\tau D_{\tau\beta})\,(\partial_\alpha \Phi)\,\bar D_{\mu\nu}) \Big\}\,. \tag{37}$$

As derived in Appendix A, the decay of the charged D^*-mesons implies

$$|g_P| = 0.57 \pm 0.07\,. \tag{38}$$

The parameter $\tilde g_P$ in (37) can not be extracted from empirical data directly. In the absence of an accurate evaluation within unquenched lattice QCD, the size of $\tilde g_P$ can be estimated using the heavy-quark symmetry of QCD. As discussed in Appendix B, one expects at leading order

$$\tilde g_P = g_P\,. \tag{39}$$

The coupling constant g_P contributes to the effective interaction $V^{(0^+)}(s)$ and $V^{(1^+)}(s)$ via s- and u-channel exchange processes of the D-meson ground states. The specific processes involved are linked to the choice of representation for the massive vector particles. In the vector representation, the propagator contains a non-propagating 0^+ component. In the tensor representation, it contains a non-propagating 1^+ component. We derive the relevant contributions applying the on-shell reduction scheme of [11].

In the scalar sector, only the u-channel exchange of the $J^P = 1^-$ contributes as a consequence of the tensor representation. We have

$$\begin{aligned}
V^{(0^+)}_{u-ch}(s) &= g_P^2\,\frac{C_{u-ch}}{4\,s\,f^2}\,\Big(s - \bar M^2 + \bar m^2\Big)\,\Big(s - M^2 + m^2\Big) \\
&\quad + g_P^2\,\frac{C_{u-ch}}{f^2}\,\int_{-1}^{1}\frac{dx}{2}\,\frac{(\bar q\cdot q)\,\mu_{1^-}^2 - (\bar m^2 - \bar q\cdot p)\,(m^2 - \bar p\cdot q)}{M^2 + \bar M^2 - \mu_{1^-}^2 - s + 2\,\bar q\cdot q}\,, \\
\bar q\cdot q &= \sqrt{\bar m^2 + \bar p_{\rm cm}^2}\,\sqrt{m^2 + p_{\rm cm}^2} - \bar p_{\rm cm}\,p_{\rm cm}\,x\,, \\
\bar q\cdot p &= -\bar q\cdot q + \frac{s - \bar M^2 + \bar m^2}{2}\,, \qquad \bar p\cdot q = -\bar q\cdot q + \frac{s - M^2 + m^2}{2}\,, \\
\sqrt{s} &= \sqrt{M^2 + p_{cm}^2} + \sqrt{m^2 + p_{cm}^2} = \sqrt{\bar M^2 + \bar p_{cm}^2} + \sqrt{\bar m^2 + \bar p_{cm}^2}\,,
\end{aligned} \tag{40}$$

where (m, M) and $(\bar m, \bar M)$ are the masses of the initial and final mesons. The parameter $\mu_{1^-} \simeq 2059$ MeV is taken to be the average of the vector D-meson masses. The coefficients $C^{(I,S)}_{u-ch}$ are given in Table 1 for the channels relevant for the formation and decay of the $D^*_{s0}(2317)$.

(I,S)	Channel	$C^{(I,S)}$	$C^{(I,S)}_{\pi,0}$	$C^{(I,S)}_{\pi,1}$	$C^{(I,S)}_{K,0}$	$C^{(I,S)}_{K,1}$	$C^{(I,S)}_{2}$	$C^{(I,S)}_{3}$	$C^{(I,S)}_{s-ch}$	$C^{(I,S)}_{u-ch}$
(0,+1)	11	2	0	0	4	0	2	0	4	0
	12	$\sqrt{3}$	0	$-\frac{\sqrt{3}}{2}$	0	$\frac{5}{2\sqrt{3}}$	0	$-\frac{1}{2\sqrt{3}}$	$\frac{4}{\sqrt{3}}$	$-\frac{2}{\sqrt{3}}$
	22	0	$-\frac{4}{3}$	$-\frac{2}{3}$	$\frac{16}{3}$	0	2	$\frac{1}{3}$	$\frac{4}{3}$	$\frac{4}{3}$
(1,+1)	11	0	4	-2	0	0	2	1	0	0
	12	1	0	$-\frac{1}{2}$	0	$-\frac{1}{2}$	0	$\frac{1}{2}$	0	-2
	22	0	0	0	4	-2	2	1	0	0

Table 1
The coefficients $C^{(I,S)}$ that characterize the interaction of Goldstone bosons with heavy-meson fields for given isospin (I) and strangeness (S). The channel indices 1 and 2 refer to the isospin basis used in [13].

As already noted in [13] the influence of the u-channel process is of very minor importance for the formation of the $D^*_{s0}(2317)$. At $f = 90$ MeV and $g_P = 0$ we obtain a mass of 2304 MeV which is pulled down by 1 MeV only if we switch on $g_P = 0.57$.

The situation is different for the axial-vector state $D^*_{s1}(2460)$. Three processes contribute: the s-channel exchange of the 1^- state and the u-channel exchanges of the 0^- and 1^- charmed mesons. The two u-channel contributions give

$$\begin{aligned}
V^{(1^+)}_{u-ch}(s) &= -\frac{C_{u-ch}}{f^2}\int\limits_{-1}^{1}\frac{dx}{4}\Big\{A_1\,(1+x^2)+\bar p_{cm}\,p_{cm}\,x\,(1-x^2)\,A_5\Big\}\,,\\
A_1 &= \frac{\tilde g_P^2}{16\,\bar M^2\,M^2\,\mu_{1^-}^2}\Big\{-\Big(M^4+(3\,\mu_{1^-}^2-u)\,M^2+\mu_{1^-}^2\,u\Big)\,\bar M^4\\
&\quad+\Big((u-3\,\mu_{1^-}^2)\,M^4+(\mu_{1^-}^2\,(2\,s-u)-u^2)\,M^2\\
&\qquad+m^2\,(M^2+\mu_{1^-}^2)\,(M^2-u)+2\,\mu_{1^-}^2\,s\,u\Big)\,\bar M^2\\
&\quad+\bar m^2\,(\bar M^2-m^2-u)\,\Big((M^2+\mu_{1^-}^2)\,\bar M^2+\mu_{1^-}^2\,(M^2+u)\Big)\\
&\quad+\mu_{1^-}^2\,(M^2+u)\,\Big((M^2-u)\,m^2+u\,(-M^2+2\,s+u)\Big)\Big\}\,,\\
A_5 &= \frac{g_P^2}{u-\mu_{0^-}^2}+\tilde g_P^2\left(1+\frac{(M^2+\bar M^2+u)\,\mu_{1^-}^2}{M^2\,\bar M^2}\right)\frac{M^2+\bar M^2-s-u}{8\,\mu_{1^-}^2\,(u-\mu_{1^-}^2)}\,,\\
&\qquad u=\bar M^2+M^2-s+2\,\bar q\cdot q\,, \qquad\qquad (41)
\end{aligned}$$

where the kinematics is given by (40). We use $\mu_{0^-} = 1918$ MeV as the average mass of the 0^- charmed mesons. The influence of the u-channel exchange interaction (41) on the formation of the $D^*_{s1}(2460)$ state is somewhat more important than it is in the scalar sector. For $f = 90$ MeV and $g_P = \tilde{g}_P = 0$, we obtain 2441 MeV, a mass which is pushed up by 5 MeV upon incorporation of (41) with $g_P = \tilde{g}_P = 0.57$. The effect is dominated largely by the exchange of the 1^- state.

We turn to the s-channel exchange. In contrast to [13] based on the vector-field representation of the spin-one D-mesons, there is a contribution from the s-channel exchange of the 1^- state within the tensor-field approach,

$$V^{(1^+)}_{s-ch}(s) = \frac{2\,\tilde{g}_P^2}{3\,\mu^2_{1^-}}\,\frac{C_{s-ch}}{4\,s\,f^2}\left(s - \bar{M}^2 + \bar{m}^2\right)\left(s - M^2 + m^2\right), \tag{42}$$

where the coefficients $C^{(I,S)}_{s-ch}$ are given in Table 1. The combined effect of (41) and (42) yields a resonance mass of 2432 MeV for $f = 90$ MeV and $g_P = \tilde{g}_P = 0.57$.

We turn to the local 2-body interaction terms, considering successively the chiral symmetry breaking and the chiral symmetric terms introduced in [13].

At chiral order Q^2_χ, the following terms break chiral symmetry explicitly,

$$\begin{aligned}\mathcal{L}_{\chi-SB} = & -2\,c_1\,D\,\chi_0\,\bar{D} - (4\,c_0 - 2\,c_1)\,(D\,\bar{D})\,\mathrm{tr}\,\chi_0 \\ & + \frac{2\,c_0 - c_1}{f^2}\,D\,\bar{D}\,\mathrm{tr}\left(\Phi\,\chi_0\,\Phi\right) + \frac{c_1}{4\,f^2}\,D\left\{\Phi,\left\{\Phi\,,\chi_0\right\}\right\}\bar{D} \\ & + \tilde{c}_1\,D_{\alpha\beta}\,\chi_0\,\bar{D}^{\alpha\beta} + (2\,\tilde{c}_0 - \tilde{c}_1)\,(D_{\alpha\beta}\,\bar{D}^{\alpha\beta})\,\mathrm{tr}\,\chi_0 \\ & - \frac{2\,\tilde{c}_0 - \tilde{c}_1}{2\,f^2}\,D_{\alpha\beta}\,\bar{D}^{\alpha\beta}\,\mathrm{tr}\left(\Phi\,\chi_0\,\Phi\right) - \frac{\tilde{c}_1}{8\,f^2}\,D_{\alpha\beta}\left\{\Phi,\left\{\Phi\,,\chi_0\right\}\right\}\bar{D}^{\alpha\beta}\,,\end{aligned} \tag{43}$$

where the matrix χ_0 is defined in (8). The parameters c_1 and $\tilde{c}_1$ are determined by the empirical mass differences of the $J^P = 0^-$ and $J^P = 1^-$ charmed mesons. According to [13] we have

$$c_1 \simeq 0.44\,, \qquad\qquad \tilde{c}_1 \simeq 0.47\,. \tag{44}$$

The parameters c_0 and $\tilde{c}_0$ could in principle be determined by unquenched lattice QCD simulation upon studying the pion- and kaon-mass dependence of the D-meson ground states. So far they are unknown. We construct the effective interaction

$$V^{(0^+)}_{\chi-SB}(s) = 2\,\frac{m_\pi^2}{f^2}\left(c_0\,C_{\pi,0} + c_1\,C^{(I,S)}_{\pi,1}\right) + 2\,\frac{m_K^2}{f^2}\left(c_0\,C_{K,0} + c_1\,C_{K,1}\right),$$

$$V^{(1^+)}_{\chi-SB}(s) = \frac{2}{3\,\bar{M}\,M}\, V^{(0^+)}_{\chi-SB}(s)\Big|_{c_i\to\tilde{c}_i} + \cdots\,, \tag{45}$$

where the dots represent higher order terms that we neglect. The coefficients $C^{(I,S)}_{\pi,0}, C^{(I,S)}_{\pi,1}, C^{(I,S)}_{K,0}$ and $C^{(I,S)}_{K,1}$ are given in Table 1.

The chiral symmetric terms of order-Q^2_χ contributing to s-wave scattering are

$$\begin{aligned}\mathcal{L}_{CT} =\;& \frac{2\,c_2 + c_3}{f^2}\, D\,\bar{D}\,\mathrm{tr}\Big((\partial_\mu\Phi)\,(\partial^\mu\Phi)\Big) - \frac{c_3}{f^2}\, D\,(\partial_\mu\Phi)\,(\partial^\mu\Phi)\,\bar{D}\\ &- \frac{2\,\tilde{c}_2 + \tilde{c}_3}{2\,f^2}\, D_{\alpha\beta}\,\bar{D}^{\alpha\beta}\,\mathrm{tr}\Big((\partial_\mu\Phi)\,(\partial^\mu\Phi)\Big) + \frac{\tilde{c}_3}{2\,f^2}\, D_{\alpha\beta}\,(\partial_\mu\Phi)\,(\partial^\mu\Phi)\,\bar{D}^{\alpha\beta}\,.\end{aligned} \tag{46}$$

They imply the effective s-wave interactions

$$\begin{aligned}V^{(0^+)}_{CT}(s) &= \Big(c_2\,\frac{C_2}{s\,f^2} + c_3\,\frac{C_3}{s\,f^2}\Big)\,\Big(s-\bar{M}^2+\bar{m}^2\Big)\,\Big(s-M^2+m^2\Big)\,,\\ V^{(1^+)}_{CT}(s) &= \frac{2}{3\,\bar{M}\,M}\, V^{(0^+)}_{CT}(s) + \cdots\,,\end{aligned} \tag{47}$$

where the dots represent again higher order terms. The coefficients $C^{(I,S)}_2$ and $C^{(I,S)}_3$ are given in Table 1. The full effective interactions $V^{(0^+)}(s)$ and $V^{(1^+)}(s)$ are then defined as the sums

$$V(s) = V_{WT}(s) + V_{u-ch}(s) + V_{s-ch}(s) + V_{\chi-SB}(s) + V_{CT}(s). \tag{48}$$

The number of unknown parameters, $c_{0,2,3}$ and $\tilde{c}_{0,2,3}$ appears large at first. A free fit to the masses of the $D^*_{s0}(2317)$ and $D^*_{s1}(2460)$ states only would not be significant. Additional constraints from QCD should be used. According to [13], the parameters c_i and $\tilde{c}_i$ are degenerate in the heavy-quark mass limit, i.e. we expect

$$c_i \simeq \tilde{c}_i\,. \tag{49}$$

It is reassuring that the values for c_1 and $\tilde{c}_1$ given in (44) are quite compatible with the expectation of the heavy-quark symmetry relations (49). We consider further constraints from QCD as they arise in the limit of a large number of colors N_c [45]. Since at leading order in a $1/N_c$ expansion single-flavour trace interactions are dominant, the corresponding couplings should go to zero in the $N_c \to \infty$ limit, suggesting

$$c_0 \simeq \frac{c_1}{2}\,, \qquad c_2 \simeq -\frac{c_3}{2}\,, \qquad \tilde{c}_0 \simeq \frac{\tilde{c}_1}{2}\,, \qquad \tilde{c}_2 \simeq -\frac{\tilde{c}_3}{2}\,. \tag{50}$$

$J^P_{(I,S)}$	$0^+_{(0,1)}$	$0^+_{(0,1)}$	$0^+_{(\frac{1}{2},0)}$	$1^+_{(0,1)}$	$1^+_{(0,1)}$	$1^+_{(\frac{1}{2},0)}$

Table 2
Masses, widths and coupling constants for dynamically generated 0^+ and 1^+ states. The coupling constants g_i corresponds to specific decay channels labeled in the isospin basis used in [13]. We use $f = 90$ MeV, $g_P = \tilde{g}_P = 0.57$, $c_3 = 1.0$, $\tilde{c}_3 = 1.4$. The remaining parameters are implied by the relations (44, 49, 50).

In the combined heavy-quark and large-N_c limit (49, 50), we are left with one free parameter only, $c_3 = \tilde{c}_3$. The optimal value $c_3 = \tilde{c}_3 = 1.2$ (together with the parameters c_1 and $\tilde{c}_1$ given by (44), $g_P = \tilde{g}_P = 0.57$ and $f = 90$ MeV) predicts 2330 MeV and 2448 MeV for the masses of the $D^*_{s0}(2317)$ and $D^*_{s1}(2460)$ states respectively.

For the determination of the width parameters, it is important to reproduce the masses accurately. We allow therefore for small variations of the parameters around the heavy-quark scenario, leaving the large-N_c relations (50) untouched. A precise reproduction of the scalar and axial-vector state masses is achieved with $c_3 = 1.0$ and $\tilde{c}_3 = 1.4$. Detailed results are collected in Table 2. For the mixing angle $\epsilon = 0.01$, the strong decay widths of the $D^*_{s0}(2317)$ and $D^*_{s1}(2460)$ are both 0.14 MeV. These widths are significantly larger than the leading order estimates discussed above. This effect is mainly a consequence of somewhat larger coupling constants $g^{(0^+)}_{\eta D_s} = 2.50$ and $g^{(1^+)}_{\eta D^*_s} = 2.42$ given in Table 2 (where they are denoted by g_2). The sensitivity to the mixing angle ϵ is illustrated by the 3rd and 6th row. Taking $\epsilon = 0.02$ instead of $\epsilon = 0.01$ leads to a strong width of 0.25 MeV rather than 0.14 MeV.

We briefly comment on the previous results of [13]. In that work a different scenario was investigated. Using the conventional vector-field representation of the 1^- charmed mesons, it was assumed that the axial-vector resonance $D^*_1(2420)$ was a member of the exotic sextet, predicted at leading order by chiral coupled-channel dynamics [12,13]. The crucial question is whether chiral correction terms reduce the weak attraction predicted at leading order or possibly enhance it. This is clearly sensitive to the implementation of chiral symmetry. For example, in [16,17] based on the broken SU(4) flavour symmetry, the sextet states are weakly bound only and therefore quite broad. In [13] chiral correction terms were tuned in such a way as to pull down the exotic axial state with (I,S) = $(\frac{1}{2}, 0)$ to match the properties of the $D_1^*(2420)$. The invariant πD and πD^* mass distributions as measured by the BELLE collaboration [46] were used as an additional constraint. It was argued that the scalar heavy-quark partner of the exotic axial state decouples from the πD channel and therefore is not seen in the data. Based on the large-N_c relations, that were not considered in [13], we would deem this scenario unlikely. In order to compare to the large-N_c scenario advocated in the present work we included in Table 2 the rows 4 and 7, which give the characteristics of the exotic $(\frac{1}{2}, 0)$ states. Like in [13] the scalar state is quite narrow with a mass below the ηD threshold. We obtain a mass and a width of 2411 MeV and 2.2 MeV respectively. As seen from the coupling constants in Table 2, the state couples most strongly to the ηD and $K\, D_s$ channels.

In Fig. 3 we confront the imaginary part of the $\pi D \to \pi D$ amplitude with the invariant πD mass distribution measured by the BELLE collaboration [46]. Such a comparison is approximate since it does not resolve the structure of the initial state. The empirical distribution is dominated by the broad $(\frac{1}{2}, 0)$ state, a member of an antitriplet like the $D_{s0}^*(2317)$, and the tensor state $D_2^*(2460)$. The contribution of this state is illustrated by the histograms. The possible presence of a narrow $(\frac{1}{2}, 0)$ state is not excluded by the present data. It is interesting to observe that the exotic state leads to a dip in the mass distribution rather than a peak. This is a consequence of the nearby ηD channel that couples strongly to that state. With the exception of a strong cusp effect at the $\bar K D$ threshold in the $(0, -1)$ sector, there is no further strong signal of any sextet state in this scenario.

A striking prediction of the large-N_c scenario is a clear measurable signal of an exotic axial state in the ηD^* invariant mass distribution with a mass of 2568 MeV. It lies above the ηD^* threshold and has a width of about 18 MeV. In Fig. 3 we confront the imaginary part of the $\pi D^* \to \pi D^*$ amplitude with the invariant πD^* mass distribution measured by the BELLE collaboration [46]. The empirical distributions show two axial and one tensor states. The contribution of the tensor state is again illustrated by the histograms. In conventional approaches the tensor state $D_2^*(2460)$ is grouped together with the $D_1^*(2420)$ state to form a heavy-quark multiplet. Within the hadrogenesis conjecture we would expect to generate that multiplet dynamically via coupled-channel effects once the light vector mesons are considered as additional and explicit degrees of freedom. The theoretical amplitude of the present work describes only the broad state, which has a width of about 300 MeV. In contrast to the πD distribution shown in the left panel of Fig. 3, we do not predict any significant signal in the πD^* distribution that one may use to discover the exotic axial state. This reflects a coupling constant of that state to the πD^* channel that is almost compatible with zero. Nonetheless, the exotic axial state could be discovered by ongoing experiments once the invariant ηD^*

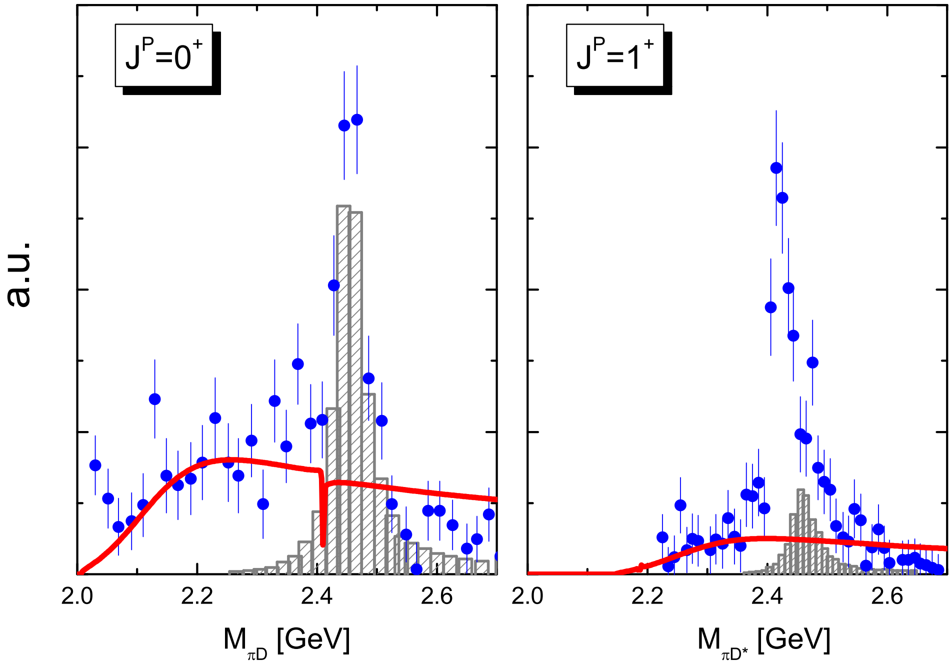

Fig. 3. Mass spectra of the $(\frac{1}{2}, 0)$-resonances as seen in the $\pi\,D(1867)$-channel (l.h. panel $J^P = 0^+$) and $\pi\,D^*(2008)$-channel (r.h. panel $J^P = 1^+$). The solid lines show the theoretical mass distributions. The data are obtained from the $B \to \pi\,D(1867)$ and $B \to \pi\,D^*(2008)$ decays [46]. The histograms indicate the contribution from the $J = 2$ resonances $D_2^*(2460)$ as given in [46].

mass distribution is analyzed. The discovery of the scalar state would require a measurement of the πD invariant mass with an energy resolution of a few MeV as may be possible with the PANDA experiment at FAIR.

We close this section with the remark that very similar results are obtained with the vector-field representation once the parameters are chosen in accordance with the expectation of large-N_c QCD rather than with the fitting procedure recalled above [13,47].

3 Electromagnetic interactions

To compute the radiative decay of the scalar and axial-vector states generated in the last section we need to couple the photon to the hadronic fields, ensuring consistency with the U(1) gauge symmetry of electromagnetic interactions. We consider first the electromagnetic interactions obtained by gauging the hadronic interactions of Section 2. We add terms involving Goldstone and D-meson fields which are separately gauge-invariant and of chiral order Q_χ^2.

Such terms are not sufficient to reproduce the available data satisfactorily. We introduce an additional 4-point vertex of order Q_χ^3 to evaluate the need to include higher chiral orders. With such a term, the data on the radiative decays of the $D_{s0}^*(2317)$ and $D_{s1}^*(2460)$ mesons can be understood at the expense of an unnaturally large value for the coupling constant of the term of order Q_χ^3. We expect this result to reflect the effectiveness of the underlying theory and more precisely the absence of light vector mesons in the dynamics of radiative transitions. We introduce them as additional explicit degrees of freedom and will indeed find that this leads to natural values of all the parameters, justifying a posteriori this extension of the theory. Light vector mesons are not included in the coupled-channel part of this work but should become part of that scheme in a later stage to study the formation of tensor states, in particular the low-lying 2^+ state expected at 2573 MeV.

We gauge the hadronic Lagrangians (6, 24, 37) using the covariant derivatives

$$\partial_\mu \Phi + i\, e\, [Q, \Phi]\, A_\mu \,, \qquad\qquad \partial_\mu D + i\, e\, D\, Q'\, A_\mu \,, \tag{51}$$

where $e = |e|$ and the charge matrices are defined by

$$Q = \begin{pmatrix} \frac{2}{3} & 0 & 0 \\ 0 & -\frac{1}{3} & 0 \\ 0 & 0 & -\frac{1}{3} \end{pmatrix}, \qquad\qquad Q' = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{52}$$

The radiative decays of the $\mathrm{D}_{s0}^*(2317)$ and $\mathrm{D}_{s1}^*(2460)$ mesons will involve only 3-point and 4-point vertices. Gauging 4-point vertices, such as the Weinberg-Tomozawa terms in (6) and (24) or the chiral correction terms (46), would lead to 5-point vertices of no relevance. The kinetic terms in (6) and (24) imply the 3-point couplings

$$\begin{aligned}\mathcal{L}_{\mathrm{e.m.}} = i\,\frac{e}{2}\, A^\mu \,\mathrm{tr}\, \Big((\partial_\mu \Phi)\, [Q,\, \Phi]_- \Big) + i\, e\, A^\mu \Big(D\, Q' (\partial_\mu\, \bar D) - (\partial_\mu\, D)\, Q'\, \bar D \Big) \\ - i\, e\, A_\mu\, D_{\mu\nu}\, Q'\, (\partial^\beta \bar D_{\beta\nu}) + i\, e\, A_\mu\, (\partial_\alpha D^{\alpha\nu})\, Q'\, \bar D_{\mu\nu} \,.\end{aligned} \tag{53}$$

Given the interactions (6, 24, 53) only, the electromagnetic decay amplitudes $0^+ \to \gamma\, 1^-$ and $1^+ \to \gamma\, 0^-$ or $\gamma\, 1^-$ are zero identically as already noted in [48]. These decay processes probe on the other hand the 3-point hadronic vertices introduced in (37). The importance of these terms in determining decays contrasts with the minor role they play for the formation of the $D_{s0}^*(2317)$ and $D_{s1}^*(2460)$ states. The gauging of the interaction (37) yields the terms

$$
\begin{aligned}
\mathcal{L}_{e.m.} =& -\frac{e\,g_P}{f}\Big\{D_{\mu\nu}\,[Q,\Phi]\,A_\mu\,(\partial^\nu\bar{D}) - (\partial^\nu D)\,[Q,\Phi]\,A^\mu\,\bar{D}_{\mu\nu}\Big\}\\
&+\frac{e\,g_P}{f}\Big\{D_{\mu\nu}\,(\partial^\mu\Phi)\,A^\nu\,Q'\,\bar{D} + A^\nu D\,Q'\,(\partial^\mu\Phi)\,\bar{D}_{\mu\nu}\Big\}\\
&+i\,\frac{e\,\tilde{g}_P}{4\,f}\,\epsilon^{\mu\nu\alpha\beta}\Big\{D_{\mu\nu}\,[Q,\Phi]\,A_\alpha\,(\partial^\tau\bar{D}_{\tau\beta}) + (\partial^\tau D_{\tau\beta})\,[Q,\Phi]\,A_\alpha\,\bar{D}_{\mu\nu}\Big\}\\
&-i\,\frac{\tilde{g}_P}{4\,f}\,\epsilon^{\mu\nu\alpha\beta}\Big\{D_{\mu\nu}\,(\partial_\alpha\Phi)\,A^\tau\,Q'\bar{D}_{\tau\beta} - A^\tau\,D_{\tau\beta}\,Q'\,(\partial_\alpha\Phi)\,\bar{D}_{\mu\nu}\Big\}\,. \qquad (54)
\end{aligned}
$$

These terms are part of the gauge-invariant vertex associated with a leading chiral power Q_χ, hence showing that the standard counting scheme requires the photon field A_μ to be of order Q_χ.

We construct the chiral correction terms of order Q_χ^2. They are gauge-invariant separately as they involve the electromagnetic field strength tensor $F_{\mu\nu}$ (of chiral order Q_χ^2). Terms of a similar structure were discussed previously, for example in [48], using a Lagrangian where massive spin 1 fields were described in the vector representation. Clearly the Lorentz structure of these terms will be different in our case.

Chiral correction terms of order Q_χ^2 describe anomalous processes. A photon hitting a pseudoscalar charmed meson may convert the latter into its heavy-quark partner, a charmed vector meson. In the absence of such processes the decay amplitudes $D^* \to \gamma\, D$ and $D_s^* \to \gamma\, D_s$ would vanish identically, contrary to experiment. The leading order anomalous vertex should be of the form

$$
\begin{aligned}
\mathcal{L}_{\text{e.m.}} = \frac{1}{2\,M_V^2}\,F^{\mu\nu}\,\epsilon_{\mu\nu\alpha\beta}\Big\{&(\partial_\tau D^{\tau\beta})\Big(e_C + e_Q\,Q\Big)\,(\partial^\alpha\bar{D})\\
&+(\partial^\alpha D)\Big(e_C + e_Q\,Q\Big)\,(\partial_\tau\bar{D}^{\tau\beta})\Big\}\,. \qquad (55)
\end{aligned}
$$

The vertices (55) carry the leading chiral power Q_χ^2 [48,49,50]. The radiative decay properties of the charmed vector mesons suggest (see Appendix A)

$$
e_Q = 0.91 \pm 0.10\,, \qquad e_C = 0.13 \pm 0.05\,. \qquad (56)
$$

The values of e_Q and e_C given in (56) reproduce the empirical branching ratios of the $D^{*-} \to D^-\,\gamma$ and $D^{*0} \to D^0\,\gamma$ decays. The data on the $D_s^* \to D_s\,\gamma$ and $D_s^* \to D_s\,\pi^0$ suggest the smaller value $e_Q \simeq 0.52$ (see Appendix A). The anomalous interaction (55) by itself is at odds with the heavy-quark symmetry of QCD which relates the interactions of pseudoscalar and vector D-mesons. Additional terms are required for consistency to parameterize the magnetic moments of the charmed vector mesons. They read

$$\mathcal{L}_{\mathrm{e.m.}} = \frac{i}{M_V^2}\, F^{\mu\nu}\,(\partial^\alpha D_{\alpha\mu})\,\Big(e\,Q' - \tilde{e}_C + \tilde{e}_Q\,Q\Big)\,(\partial^\beta \bar{D}_{\beta\nu})\,. \tag{57}$$

The parameters $\tilde{e}_C$ and $\tilde{e}_Q$ are related to the magnetic moments of the charmed vector mesons by [41,42,43]

$$\mu_{D_0^*} = \frac{M_{D_0^*}}{2\,M_V^2}\,\Big(\tilde{e}_C - \frac{2}{3}\,\tilde{e}_Q\Big)\,, \qquad \mu_{D_+^*} = \frac{M_{D_+^*}}{2\,M_V^2}\,\Big(\tilde{e}_C + \frac{1}{3}\,\tilde{e}_Q\Big)\,,$$
$$\mu_{D_s^*} = \frac{M_{D_s^*}}{2\,M_V^2}\,\Big(\tilde{e}_C + \frac{1}{3}\,\tilde{e}_Q\Big)\,. \tag{58}$$

At present there is no empirical information on these magnetic moments of help to determine the values of $\tilde{e}_C$ and $\tilde{e}_Q$. Note that the term proportional to Q' in (57) cancels a corresponding contribution which is implied by minimally gauging the kinetic term (53).

It is instructive to interpret the result (58) in terms of the constituent quark model. The contribution from $\tilde{e}_C$ reflects the magnetic moment of the charm quark. It is SU(3) flavour-blind. In the heavy-quark mass limit, the parameter $\tilde{e}_C$ approaches a constant. In contrast, the term proportional to $\tilde{e}_Q$ models the contribution of the magnetic moment of the light quark. It is flavour-dependent, being proportional to the charge matrix of the light quarks Q. In the heavy-quark mass limit, $\tilde{e}_Q$ scales linearly with the charm quark mass. To leading order, the parameters $\tilde{e}_C$ and $\tilde{e}_Q$ are related to e_C and e_Q by (see Appendix B)

$$e_Q = \tilde{e}_Q\,, \qquad e_C = \tilde{e}_C\,. \tag{59}$$

We emphasize that the two sets of terms (55) and (57) are the only chiral corrections to the leading order Lagrangian at order Q_χ^2. It does not appear possible to fit the data on the $D_{s0}^*(2317)$ and $D_{s1}^*(2460)$ radiative decays with these electromagnetic terms together with the Lagrangians (53) and (54) (see Section 6 for details). This suggests that higher order terms should be considered. We introduce an additional term involving one Goldstone boson field and proportional to $F_{\mu\nu}$ and to the charge matrix Q of the light quarks (expected to be dominant in the heavy-quark mass limit [48]),

$$\begin{aligned}\mathcal{L}_{\mathrm{e.m.}} = {}& \frac{e_P}{f\,m_V^2}\,F^{\mu\nu}\,\Big\{D_{\mu\alpha}\,[(\partial_\nu\Phi),Q]\,(\partial^\alpha\bar{D}) - (\partial^\alpha D)\,[(\partial_\nu\Phi),Q]\,\bar{D}_{\mu\alpha}\Big\}\\ & - i\,\frac{\tilde{e}_P}{4\,f\,m_V^2}\,F_{\mu\nu}\,\epsilon^{\sigma\tau\mu\beta}\,\Big\{D_{\sigma\tau}\,[(\partial^\nu\Phi),Q]\,(\partial^\alpha\bar{D}_{\alpha\beta})\\ & \qquad + (\partial^\alpha D_{\alpha\beta})\,[(\partial^\nu\Phi),Q]\;\bar{D}_{\sigma\tau}\Big\}\,.\end{aligned} \tag{60}$$

The heavy-quark symmetry predicts the relation (see Appendix B)

$$e_P = \tilde{e}_P \,. \tag{61}$$

One expects $|e_P| \sim e \simeq 0.303$. According to standard counting rules the vertices (60) carry the leading chiral power Q_χ^3. It should be emphasized, however, that the counting rules depend on a naturalness assumption, i.e. that the dimensional parameters of the effective Lagrangian density scale with appropriate power of the chiral symmetry breaking scale $4\pi\, f \simeq 1131$ MeV (or more pragmatically with the mass m_V of the lightest degree of freedom that is integrated out). This is the rationale behind the particular representation of the vertex (60) in terms of the dimensionless parameters e_P and $\tilde{e}_P$. One may assign the vertex (60) the order Q_χ^2. On a formal level that would justify to consider the effect of (60) while neglecting additional hadronic vertices of chiral order Q_χ^3, such as the SU(3) flavour breaking effects in the coupling of the Goldstone bosons to the D mesons (see (37)).

There is no empirical estimate available of the size of e_P and $\tilde{e}_P$, in particular no data on the three-body decay process $D^{*+} \to \gamma\, \pi^+ \, D^0$ sensitive to e_P. These parameters have therefore to be determined indirectly. We shall see in the section on numerical results that the magnitude of the parameter e_P is larger than expected from the naive naturalness assumption if we try to reproduce the data with the effective Lagrangian derived above. Such a phenomenon is not unusual in effective field theories, though asking for a physical explanation. We assume that the size of e_P is a manifestation of the need to incorporate additional degrees of freedom, the most natural ones being the light vector mesons. Once they are incorporated one expects the fitted value of e_P to reduce significantly. We take this as a motivation to explore the role played by the light vector mesons in the radiative decays of the $D^*_{s0}(2317)$ and $D^*_{s1}(2460)$ states.

3.1 Light vector mesons

For the light vector mesons, there is no well-defined chiral power counting scheme to the authors' knowledge, at least for the case of virtual vector mesons. The treatment of these degrees of freedom is therefore more phenomenological than the chiral expansion approach used for Goldstone bosons and heavy-light mesons. The 3-point electromagnetic vertex probed when considering the light vector mesons is the anomalous process analogous to (55) where a photon excites a Goldstone boson into a vector meson. It reads

$$\mathcal{L}_{\text{e.m.}} = \frac{e_A}{8\, f\, m_V}\, F^{\mu\nu}\, \epsilon_{\mu\nu\alpha\beta}\, \mathrm{tr}\Big((\partial^\alpha \Phi)\, [Q,\, \partial_\tau V^{\tau\beta}]_+ \Big)\,, \tag{62}$$

where we use the representation

$$V_{\mu\nu} = \begin{pmatrix} \rho^0_{\mu\nu} + \omega_{\mu\nu} & \sqrt{2}\,\rho^+_{\mu\nu} & \sqrt{2}\,K^+_{\mu\nu} \\ \sqrt{2}\,\rho^-_{\mu\nu} & -\rho^0_{\mu\nu} + \omega_{\mu\nu} & \sqrt{2}\,K^0_{\mu\nu} \\ \sqrt{2}\,K^-_{\mu\nu} & \sqrt{2}\,\bar{K}^0_{\mu\nu} & \sqrt{2}\,\phi_{\mu\nu} \end{pmatrix} . \tag{63}$$

The particular form (62) is equivalent to the anomalous photon coupling used for example in [51]. From the radiative decays of the light vector mesons considered in Appendix A, one derives conflicting values for the parameter e_A. A quantitative description requires the inclusion of SU(3) flavour breaking effects. Only three processes, $K^{*0} \to K^0\gamma$, $K^{*\pm} \to K^\pm\gamma$ and $\phi \to \eta\gamma$, are relevant for the radiative decays of the D^*_{s0} and D^*_{s1} states. We will include SU(3) breaking by using the phenomenological couplings obtained in Appendix A for each of these processes,

$$\begin{aligned} &|e_A^{(K^*_0 \to K_0 \gamma)}| = 0.119 \pm 0.006\,, \qquad &&|e_A^{(K^*_\pm \to K_\pm \gamma)}| = 0.090 \pm 0.004\,, \\ &|e_A^{(\,\phi\, \to \,\eta\, \gamma\,)}| = 0.053 \pm 0.001\,. \end{aligned} \tag{64}$$

The anomaly vertex (62) can contribute to the radiative decays of the D^*_s-mesons only in the presence of additional hadronic 3-point vertices. The light vector meson that is created by the photon must be absorbed by a heavy meson. The corresponding interaction is constructed by analogy with (37),

$$\begin{aligned} \mathcal{L} = {} & i\,\frac{g_V}{2\,f}\,\Big\{ D\,(\partial_\alpha V^{\alpha\mu})\,(\partial_\mu \bar{D}) - (\partial_\mu D)\,(\partial_\alpha V^{\alpha\mu})\,\bar{D} \Big\} \\ & - i\,\frac{\tilde{g}_V}{2\,f}\,\Big\{ D^{\mu\nu}\,(\partial^\alpha V_{\alpha\mu})\,(\partial^\beta \bar{D}_{\beta\nu}) - (\partial^\beta D_{\beta\nu})\,(\partial^\alpha V_{\alpha\mu})\bar{D}^{\mu\nu} \Big\} \\ & + \frac{\tilde{g}_T}{4\,f}\,\epsilon^{\mu\nu\alpha\beta}\,\Big\{ (\partial_\alpha D)\,V_{\mu\nu}\,(\partial^\tau \bar{D}_{\tau\beta}) + (\partial^\tau D_{\tau\beta})\,V_{\mu\nu}\,(\partial_\alpha \bar{D}) \Big\} \\ & + i\,\frac{g_T}{2\,f}\,(\partial^\alpha D_{\alpha\mu})\,V^{\mu\nu}\,(\partial^\beta \bar{D}_{\beta\nu}) \\ & + \frac{g_E}{4\,f}\,\epsilon_{\mu\nu\alpha\beta}\,\Big\{ D^{\mu\nu}\,(\partial_\tau V^{\tau\beta})\,(\partial^\alpha \bar{D}) + (\partial^\alpha D)\,(\partial_\tau V^{\tau\beta})\,\bar{D}^{\mu\nu} \Big\}\,. \end{aligned} \tag{65}$$

The electromagnetic terms implied by the covariant derivatives (51) should be added. The particular form of (65) was guided by the Lagrangian (37) and the flavour SU(4) limit. We complement (65) by additional electromagnetic interactions analogous to (60),

$$\mathcal{L} = \frac{e_V}{2\,f\,m_V^2}\,F^{\mu\nu}\,\Big\{ D\,[(\partial_\alpha V^{\alpha\nu}),\,Q]\,(\partial_\mu \bar{D}) - (\partial_\mu D)\,[(\partial_\alpha V^{\alpha\nu}),\,Q]\,\bar{D} \Big\}$$

$$
\begin{aligned}
&- \frac{\tilde{e}_V}{2\, f\, m_V^2}\, F^{\mu\nu} \Big\{ D_{\mu\tau}\, [(\partial_\alpha V^{\alpha\nu}),\, Q]\, (\partial_\beta \bar{D}^{\beta\tau}) - (\partial_\beta D^{\beta\tau})\, [(\partial_\alpha V^{\alpha\nu}),\, Q]\, \bar{D}_{\mu\tau} \Big\} \\
&- i\, \frac{\tilde{e}_T}{4\, f\, m_V^2}\, F^{\mu\nu}\, \epsilon_{\mu\sigma\alpha\beta} \Big\{ (\partial^\alpha D)\, [V_\nu{}^\sigma,\, Q]\, (\partial_\tau \bar{D}^{\tau\beta}) \\
&\qquad\qquad + (\partial_\tau D^{\tau\beta})\, [V_\nu{}^\sigma,\, Q]\, (\partial^\alpha \bar{D}) \Big\} \\
&+ \frac{e_T}{2\, f\, m_V^2}\, F^{\mu\nu}\, (\partial^\alpha D_{\alpha\mu})\, [V^{\nu\tau},\, Q]\, (\partial^\beta \bar{D}_{\beta\tau}) \\
&- \frac{e_E}{f\, m_V^2}\, F^{\mu\nu}\, (\partial_\alpha D)\, \{V_{\mu\nu},\, Q\}\, (\partial^\alpha \bar{D}) \\
&+ \frac{\tilde{e}_E}{f\, m_V^2}\, F^{\mu\nu}\, (\partial_\alpha D^{\alpha\tau})\, \{V_{\mu\nu},\, Q\}\, (\partial^\beta \bar{D}_{\beta\tau})\,. \qquad (66)
\end{aligned}
$$

The hadronic vertices (37, 65) should also have some impact on the formation of the molecules based on the leading orders coupled-channel interaction. The influence of the parameters g_P and $\tilde{g}_P$ was studied in [13] and in Section 2.3. Their effects on the mass were found to be rather minor, confirming the expectation that the corresponding interactions are of subleading order in a chiral expansion. Nevertheless, this issue deserves further studies. In particular, the role played by additional inelastic channels involving the light vector mesons should be worked out. We anticipate that they are responsible for the formation of tensor molecules. We will return to this issue in the next section.

The various parameters in (65, 66) are correlated by the heavy-quark symmetry of QCD. As shown in Appendix B, one expects

$$
\begin{aligned}
&\tilde{g}_V = g_V\,, \qquad && \tilde{g}_T = g_T\,, \\
&e_V = \tilde{e}_V\,, && e_T = \tilde{e}_T\,, \qquad && e_E = \tilde{e}_E\,, \qquad (67)
\end{aligned}
$$

at leading order. The size of g_V and $\tilde{g}_V$ can be estimated by the phenomenological assumption of universally coupled light vector mesons and the KSFR relation to be

$$
g_V = \tilde{g}_V = \frac{g\, f}{m_V} = \frac{\pm 1}{\sqrt{2}} \simeq \pm 0.71\,, \qquad (68)
$$

with the universal vector coupling constant $|g| \simeq 6$ [52]. The phase of the coupling constant g_V is not determined by this assumption.

The estimate of the size of the coupling constants g_T and g_E is more difficult. While lacking QCD lattice simulations, we may use a flavour SU(4) ansatz, admittedly a rather rough and questionable tool. In order to do so, we introduce flavour SU(4) multiplet fields

$$V^{\mu\nu}_{[16]} = \begin{pmatrix} V^{\mu\nu} & 0 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & \sqrt{2}\,\bar{D}^{\mu\nu} \\ \sqrt{2}\,D^{\mu\nu} & J/\psi \end{pmatrix} ,$$

$$\Phi_{[16]} = \begin{pmatrix} \Phi & 0 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & \sqrt{2}\,\bar{D} \\ \sqrt{2}\,D & \eta_c \end{pmatrix} , \qquad (69)$$

in terms of the SU(3) multiplet fields Φ, D and $V_{\mu\nu}, D_{\mu\nu}$. We construct a minimal SU(4) invariant Lagrangian density that comprises the interaction terms introduced in (37, 65),

$$\begin{aligned} \mathcal{L}_{SU(4)} = {} & \frac{g_1}{4\,f}\,\epsilon_{\mu\nu\alpha\beta}\,\mathrm{tr}\,(\partial^\alpha \Phi_{[16]})\left\{\mathrm{V}^{\mu\nu}_{[16]}\,(\partial_\tau \mathrm{V}^{\tau\beta}_{[16]}) + (\partial_\tau \mathrm{V}^{\tau\beta}_{[16]})\,\mathrm{V}^{\mu\nu}_{[16]}\right\} \\ & + \frac{i\,g_2}{4\,f}\,\mathrm{tr}\,(\partial_\alpha V^{\alpha\mu}_{[16]})\,V^{[16]}_{\mu\nu}\,(\partial_\beta V^{\beta\nu}_{[16]}) - \frac{i\,g_3}{2\,f}\,\mathrm{tr}\,(\partial_\mu \Phi_{[16]})\,\mathrm{V}^{\mu\nu}_{[16]}\,(\partial_\nu \Phi_{[16]}) (70) \end{aligned}$$

The ansatz (70) suggests the identification

$$\tilde{g}_T = g_E = \tilde{g}_P = g_1\,, \qquad \tilde{g}_V = g_T = g_2\,, \qquad g_V = g_P = g_3\,. \quad (71)$$

The result (71) deserves and requires some discussion. We observe that according to (39, 67) the coupling constants g_i with $i = 1, 2, 3$ in (70) should approach a universal value in the heavy-quark mass limit, for instance the parameters g_P and g_V. Confronted with the values (38) and (68), this expectation appears verified within less than 20%. However, the result (71) would predict also a common value for g_P and g_T. We point out that this implication is troublesome: whereas g_P approaches a finite value, the parameter g_T must vanish in the heavy-quark mass limit. This is an immediate consequence of the fact that the QCD action is linear in the charm quark mass. While the term proportional to g_P involves one derivative acting on a heavy field, the term proportional to g_T involves two. It is therefore clear that we must not use the relations (71) as they stand. From (71) we retain only the predicted phase relations for the coupling constants, i.e. we assume all coupling constants to take positive values. In addition, for the unknown parameter g_E, we would anticipate the range

$$g_P \leq g_E \leq g_V\,, \qquad (72)$$

a conjecture consistent with the expected scaling behaviour at large charm-quark masses. The estimate of the remaining parameters $g_T \simeq \tilde{g}_T$ is most uncertain. From (71) we would expect the range

$$0 \leq g_T \leq \frac{m_V}{M_V}\,g_P\,, \qquad (73)$$

with $m_V = 776$ MeV and $M_V = 2000$ MeV representing the typical masses of light and heavy vector meson.

3.2 Radiative decay of molecules

We display in Fig. 4 the various graphs contributing to the radiative decay of the $D^*_{s0}(2317)$ and $D^*_{s1}(2460)$ states which are linear in the hadronic three-point vertices. The D^*_{s0} and D^*_{s1} mesons generated by coupled-channel dynamics appear as blocks, the sum of the bubble diagrams defining the effective propagator of the resonance state. It is drawn as a double line. The dynamics of the decay is contained in a single loop. Solid lines represent the propagation of the pseudoscalar or vector mesons. The thin lines stand for the light mesons and the thick lines for the heavy mesons. The wavy line is the photon.

We display in Fig. 5 two-loop diagrams which, at first sight, should be relevant for the radiative decay width of scalar and axial-vector molecules. The figure shows contributions where the photon couples to the resonance directly. We do not resolve the structure of the vertex since these diagrams vanish identically. This is an immediate consequence of using the tensor-field representation of the spin one particles. Consider for instance the decay of a scalar molecule, where the final state carries $J^P = 1^-$ quantum numbers. All diagrams in Fig. 5 factorize into two contributions. Since the left part is contracted with the antisymmetric wave function of the 1^- state, it vanishes identically. This contribution carries indeed the two indices α and β and depends on one 4-momentum only, the 4-momentum of the final state. It must be symmetric in the indices α and β and therefore vanishes if contracted with the wave function. Analogous arguments hold for the decay modes of axial-vector molecules. There are two possibilities. If the final state carries $J^P = 0^-$ quantum numbers, the antisymmetric and outgoing indices of the intermediate axial-vector

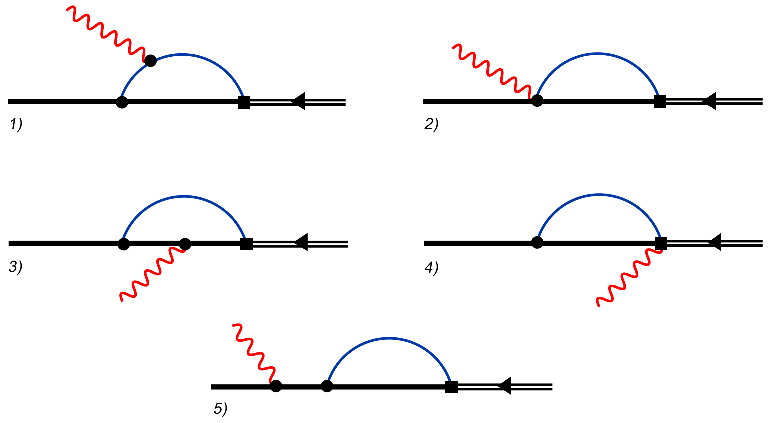

Fig. 4. Single-loop diagrams contributing to the decay amplitude of a scalar or axial-vector molecule (see text).

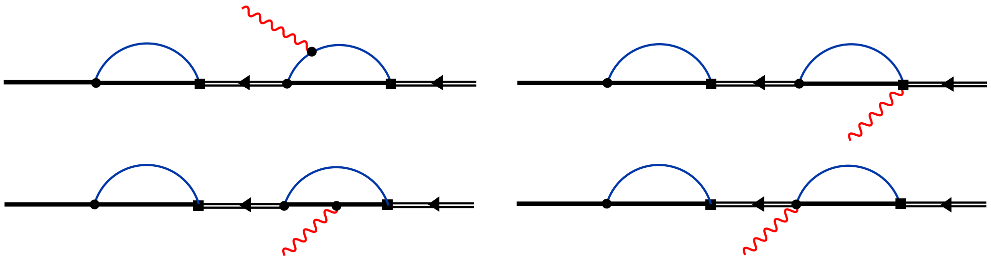

Fig. 5. Two-loop diagrams contributing to the decay width of scalar and axial-vector molecules where the photon couples to the resonance directly (see text). These terms vanish identically in the tensor representation of massive vector particles.

propagator are contracted necessarily with the 4-momentum of the final state. If the final state carries $J^P = 1^-$ quantum numbers, the final 3-point vertex involves the antisymmetric tensor $\epsilon_{\mu\nu\alpha\beta}$ due to parity conservation. At least two indices must be saturated by the 4-momentum of the 1^- D_s-meson.

A striking conclusion of our discussion is that the radiative decay of a scalar or axial-vector molecule is determined fully by an effective hadronic resonance vertex. The detailed structure of the resonance propagator is not probed. We emphasize that this is a consequence of using the tensor-field representation of spin-one particles. The application of the vector-field representation would require a detailed study of the resonance propagator. This could be quite cumbersome. In particular, enforcing gauge invariance is highly non-trivial. Our observation implies that even in the presence of the additional coupled-channel interactions (37, 65), the formal evaluation of the diagrams of Fig. 4 would be unchanged.

Because of the particular structure of the decay diagrams, it is useful to introduce flavour triplet fields, R and $R_{\mu\nu}$, which interpolate the scalar and axial-vector molecules. All what is needed are the coupling strengths of the molecules to the hadronic final states. We introduce the effective coupling constants g_R and $\tilde{g}_R$,

$$\begin{aligned}\mathcal{L}_R = &-\frac{g_R}{2\,f}\left\{(\partial_\mu D)\,(\partial^\mu \Phi)\,\bar{R} + R\,(\partial^\mu \Phi)\,(\partial_\mu \bar{D})\right\} \\ &- i\,\frac{\tilde{g}_R}{2\,f}\left\{D^{\mu\nu}\,(\partial_\mu \Phi)\,(\partial^\tau \bar{R}_{\tau\nu}) - (\partial^\tau R_{\tau\nu})\,(\partial^\mu \Phi)\,\bar{D}^{\mu\nu}\right\}, \qquad (74)\end{aligned}$$

where we do not write explicitly terms linear in the photon field that are required by gauge invariance. We may add terms involving the electromagnetic field strength tensor $F_{\mu\nu}$ that are gauge-invariant separately. Like the parameters g_R and $\tilde{g}_R$, the structure and size of these terms have to be extracted from a coupled-channel computation. As will become clear in the subsequent section, the role of such terms is very minor. Within our renormalization scheme such contributions vanish identically for the particular choice where the matching scale μ_M and the mass of the hadronic final state are degenerate. This degeneracy is almost realized. For on-shell conditions, the first vertex of (74) is equivalent to a vertex of the generic form $D\,\Phi\,\bar{R}$ as implied by the projector technique described in Section 2.1. This follows from the replacement

$$2\,(\partial_\mu D)\,(\partial^\mu \Phi)\,\bar{R} \to D\,\Phi\,(\partial^\mu \partial_\mu \bar{R}) - (\partial^\mu \partial_\mu D)\,\Phi\,\bar{R} - D\,(\partial^\mu \partial_\mu \Phi)\,\bar{R}\,. \tag{75}$$

In general the two vertices would give different results in one-loop diagrams. Within our renormalization scheme discussed in the next subsection, the vertices are equivalent. The corresponding decay amplitudes coincide up to terms that may be generated by effective molecule vertices involving $F_{\mu\nu}$. As argued above such terms vanish identically for the particular choice where the matching scale μ_M is identified with the mass of the hadronic final state. An analogous argument shows the equivalence of the second vertex of (74) with the generic form $(\partial_\alpha D^{\alpha\tau})\,\Phi\,(\partial^\beta\,\bar{R}_{\beta\tau})$ implied in Section 2.2. This vertex leads to the form (27) of the scattering amplitude for $J^P = 1^+$.

At leading order the magnitude of the parameters g_R and $\tilde{g}_R$ are determined by the coupling constants as extracted from the pole structure of the scattering amplitude (see (18, 35)). We identify

$$\begin{aligned} g_R &= \frac{4\sqrt{2}\,f\,M_{0^+}}{M_{0+}^2 - M_D^2 \; - m_K^2}\,g_{KD}^{(0+)} = \frac{4\sqrt{6}\,f\,M_{0^+}}{M_{0+}^2 - M_{D_s}^2 - m_\eta^2}\,g_{\eta D_s}^{(0+)}\,, \\ \tilde{g}_R &= \frac{4\sqrt{2}\,f\,M_{D^*}}{M_{1+}^2 - M_{D^*}^2 - m_K^2}\,g_{KD^*}^{(1+)} = \frac{4\sqrt{6}\,f\,M_{D_s^*}}{M_{1+}^2 - M_{D_s^*}^2 - m_\eta^2}\,g_{\eta D_s^*}^{(1+)}\,. \end{aligned} \tag{76}$$

As detailed in Appendix B, heavy-quark symmetry predicts

$$g_R = \tilde{g}_R\,, \tag{77}$$

at leading order. While (77) is realized quite accurately, the SU(3) flavour breaking effects in the coupling constant g_R and $\tilde{g}_R$ are sizeable as can be inferred from the values given in Table 2. The relation (77) is satisfied at the 10 % level

$$\frac{\tilde{g}_R}{g_R} \simeq 0.986\,\frac{g_{KD^*}^{(1+)}}{g_{KD}^{(0+)}} \simeq 0.989\,\frac{g_{\eta D_s^*}^{(1^+)}}{g_{\eta D_s}^{(0+)}}\,. \tag{78}$$

In contrast, the SU(3) relations

$$g_R \simeq 0.720\,g_{KD}^{(0+)} \simeq 1.710\,g_{\eta D_s}^{(0+)}\,, \qquad \tilde{g}_R \simeq 0.710\,g_{KD^*}^{(1+)} \simeq 1.691\,g_{\eta D_s^*}^{(1+)}\,, \tag{79}$$

are violated at the 95% level. The value $g_R \simeq 4.28$ derived from the ηD_s channel with $f = 90$ MeV is almost a factor of two larger than the value obtained from the KD channel.

Before turning to the renormalization issue, we discuss additional resonance vertices involving light vector mesons. The latter arise necessarily in a coupled-channel computation once any of the parameters $g_V, \tilde{g}_V, g_T, \tilde{g}_T$ or g_E is non-vanishing. Though we are not presenting results of such a computation, we study the relevance of light vector meson in radiative decay processes of scalar and axial-vector molecules. We introduce the effective resonance vertices (leaving out additional terms linear in the photon field required by gauge invariance)

$$\begin{aligned}\mathcal{L}_R = \frac{g_H}{2\,f}\Big\{R\,(\partial^\tau V_{\tau\nu})\,(\partial_\mu \bar{D}^{\mu\nu}) + (\partial_\mu D^{\mu\nu})\,(\partial^\tau V_{\tau\nu})\,\bar{R}\Big\}\\ + i\,\frac{\tilde{g}_H}{2\,f}\,\Big\{(\partial^\mu R_{\mu\nu})\,(\partial_\tau V^{\tau\nu})\,\bar{D} - D\,(\partial_\tau V^{\tau\nu})\,(\partial^\mu \bar{R}_{\mu\nu})\Big\}\\ - \frac{\hat{g}_H}{4\,f}\,\epsilon^{\alpha\beta\mu\nu}\,\Big\{(\partial^\sigma R_{\sigma\mu})\,(\partial^\tau V_{\tau\nu})\,\bar{D}_{\alpha\beta} + D_{\alpha\beta}\,(\partial^\tau V_{\tau\nu})\,(\partial^\sigma \bar{R}_{\sigma\mu})\Big\}\,,\end{aligned} \tag{80}$$

where the parameters $g_H, \tilde{g}_H$ and $\hat{g}_H$ are unknown at this stage and degenerate in the heavy-quark limit. As worked out in Appendix B, we have indeed

$$g_H = \tilde{g}_H = \hat{g}_H\,. \tag{81}$$

For the axial-vector molecules, additional vertices that are not on-shell equivalent to those of (80) may be constructed. Such terms are suppressed by their d-wave phase-space behaviour. The presence of the vertices (80) leads to additional diagrams contributing to the radiative decay amplitudes of scalar and axial-vector molecules. Such diagrams are part of Fig. 4 given the meaning of the solid lines which represent the propagation of either pseudoscalar or vector mesons.

3.3 Renormalization

We finally turn to the renormalization issue. The decay diagrams are ultraviolet divergent. Applying the Passareno-Veltman reduction [53], which is rigourously justified within dimensional regularization, the integrals of Fig. 4 may be expressed in terms of a set of scalar integrals of the form

$$I_a = -i\int \frac{d^4l}{(2\pi)^4}\,S_a(l)\,, \qquad\qquad S_a(l) = \frac{1}{l^2 - m_a^2 + i\,\epsilon}\,,$$

$$
\begin{aligned}
I_{ab} &= -i \int \frac{d^4l}{(2\pi)^4}\, S_a(l)\, S_b(l+p)\,, \qquad \bar I_{ab} = -i \int \frac{d^4l}{(2\pi)^4}\, S_a(l)\, S_b(l+\bar p)\,,\\
J_{abc} &= +i \int \frac{d^4l}{(2\pi)^4}\, S_a(l)\, S_b(l+q)\, S_c(l+p)\,,\\
\bar J_{abc} &= +i \int \frac{d^4l}{(2\pi)^4}\, S_a(l)\, S_b(l+\bar p)\, S_c(l+p)\,, \qquad (82)
\end{aligned}
$$

where we focus on the physical limit with space-time dimension four. In our convention the 4-momentum p_μ characterizes the decaying molecule, q_μ is the 4-momentum of the photon and $\bar p_\mu = p_\mu - q_\mu$ is the 4-momentum of the hadronic final state. The quantities defined in (159)are evaluated in Appendix C.

Divergent structures arise only from the tadpole integral I_a and the two-propagator integrals I_{ab} and $\bar I_{ab}$. Since the combinations

$$
I_{ab} - \bar I_{ab}\,, \qquad\qquad I_{ab} - \frac{I_b - I_a}{m_a^2 - m_b^2}\,, \qquad (83)
$$

are finite as space-time dimension approaches four, one may take the viewpoint that all divergent structures are caused by the tadpole integral I_a (see also [54]).

Any divergent contribution can not be renormalized by simply adding a counter vertex where the photon couples directly to the resonance. Since the resonance is formed by coupled-channel dynamics its radiative decays amplitude must be renormalized by a loop subtraction mechanism similar to the one introduced in [55]. This is illustrated in Fig. 6. Typically the counter terms needed are appropriate 5-point vertices as indicated in Fig. 6 by an solid square. A contribution to the radiative decay amplitude is generated by contracting two identical lines giving rise to a tadpole-type contribution. The latter have to cancel the tadpole contributions from Fig. 4 as discussed above.

There is yet another important observation to make. In Fig. 4 the integral arising from the second and fourth diagrams have a structure similar to the

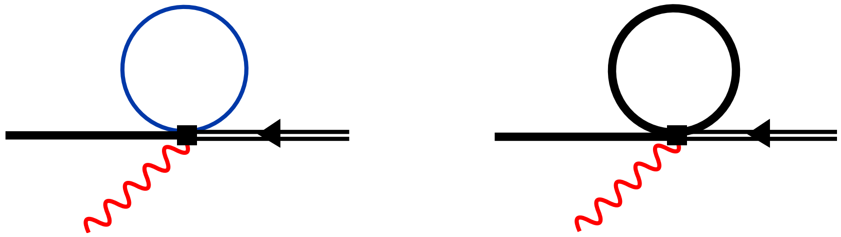

Fig. 6. Examples of counter loop contributions that renormalize the decay amplitude of molecules.

loop functions that build up the resonance state. Therefore the renormalization of the coupled-channel dynamics and of the radiative-decay amplitude are necessarily related. Since the coupled-channel dynamics involves an infinite number of Feynman diagrams, one has to leave the well-trotted path of perturbative renormalization, i.e. infinite sets of counter terms present in effective field theories have to be introduced at each order. We emphasize that one should carefully discriminate two issues. First, the renormalization scale independence of a scattering amplitude and second, a possible scheme dependence of how the infinite number of diagrams are treated. We point out that the application of the on-shell reduction formalism developed in [55,33,11], as is implied by the unique existence of an algebra of covariant projectors, may be considered as a scheme dependence. The additional ingredient, the requirement of a smooth matching of scattering amplitudes unitarized in different channels, can be considered again as a scheme dependence. It is an economical, though not unique, procedure to build crossing symmetry into the scheme. From this point of view the matching parameter μ_M in (14, 29) reflects a scheme dependence, not a renormalization scale dependence.

As a consequence of the on-shell reduction formalism our coupled-channel dynamics is based on, neither the effective potential $V^{(JP)}(s)$ nor the loop functions $J^{(JP)}(s)$ gain any contribution at leading order from a tadpole-type loop integral I_a. Using the leading order two-body interaction as the driving force of a Bethe-Salpeter equation would introduce plenty of tadpole contributions [33,11]. As was discussed in great detail in [33,11], the contribution of reduced tadpoles can be trusted only at a level where one computes one-loop corrections to the Bethe-Salpeter interaction kernel, i.e. for two-particle irreducible diagrams. While for the latter conventional power-counting arguments are applicable, they are not for the reducible contributions, i.e. those summed by the unitarization.

Closing our chain of arguments, we arrive at the result that reduced tadpole contributions in the decay amplitude should be dropped in our leading order computation. In addition a finite renormalization is applied to the integral I_{ab}. It is identified with the expression introduced in (15) with

$$I_{ab} = I(p^2) - I(\mu_M^2)\,, \qquad\qquad m_a = M\,, \qquad m_b = m\,, \tag{84}$$

and the matching scale μ_M used in the coupled-channel computation.

4 Radiative decay of scalar molecules: $D^*_{s0}(2317) \to \gamma\, D^*_s(2112)$

We express the partial decay width $\Gamma_{0^+\to\gamma\,1^-}$ of the $D^*_{s0}(2317)$-meson in terms of the transition amplitudes $M^{\alpha\beta,\mu}_{0^+\to\gamma\,1^-}$. Due to gauge invariance, the transition tensor is characterized by a single number $d_{0^+\to\gamma\,1^-}$ defined by

$$\begin{aligned}&\epsilon^\dagger_\mu(q,\lambda_q)\,\epsilon^\dagger_{\alpha\beta}(\bar p,\lambda_{\bar p})\,M^{\alpha\beta,\mu}_{0^+\to\gamma\,1^-}\\ &\qquad = d_{0^+\to\gamma\,1^-}\;\epsilon^\dagger_\mu(q,\lambda_q)\,\epsilon^\dagger_{\alpha\beta}(\bar p,\lambda_{\bar p})\,\Big\{g^{\mu\alpha}\,(p\cdot q)-p^\mu\,q^\alpha\Big\}\,\frac{i\,\bar p^\beta}{\sqrt{\bar p^2}}\,,\end{aligned} \tag{85}$$

where $\epsilon_\mu(q,\lambda_q)$ and $\epsilon_{\alpha\beta}(\bar p,\lambda_{\bar p})$ denote the wave functions of the outgoing photon and vector meson and $p_\mu = \bar p_\mu + q_\mu$ the decaying resonance momentum. The radiative width reads

$$\Gamma_{0^+\to\gamma\,1^-} = \frac{|d_{0^+\to\gamma\,1^-}|^2}{4\pi}\left(\frac{M^2_{0^+}-M^2_{1^-}}{2\,M_{0^+}}\right)^3\,, \tag{86}$$

with $M^2_{1^-}=\bar p^2$ and $M^2_{0^+}=p^2$. The decay parameter can be obtained by the projection formula,

$$d_{0^+\to\gamma\,1^-} = \frac{-i}{(p\cdot q)\,M_{1^-}}\left\{g_{\mu\alpha}-\frac{p_\mu\,q_\alpha}{(p\cdot q)}\right\}\bar p_\beta\,M^{\alpha\beta,\mu}_{0^+\to\gamma\,1^-}\,, \tag{87}$$

since the decay amplitude is transverse with respect to the photon momentum and antisymmetric in the indices $\alpha\leftrightarrow\beta$. This implies that the off-shell amplitude $\bar p_\beta\,M^{\alpha\beta,\mu}$ is orthogonal to q_μ and $\bar p_\alpha$, i.e. is characterized by two parameters only. With (87) we project onto the relevant component.

There are 5 classes of contributions as shown in Fig. 4. All terms have the topology of a one-loop Feynman diagram. A given contribution is either proportional to the coupling constant g_R or g_H. The thin line attached to the resonance vertex represents the propagation of a pseudoscalar (g_R) or a vector meson (g_H) and the thick line the propagation of a heavy meson. The outgoing line represents a vector D^*_s meson.

It is convenient to group together diagrams that are gauge-invariant separately. We discuss the various contributions proportional to the coupling constant g_R. We consider first the terms of class 2) in Fig. 4. They are proportional to $e\,g_P/f$ and involve two types of tensors. We form two gauge-invariant combinations with the transverse tensors $A^{\alpha\beta,\mu}(\bar p,p)$ and $B^{\alpha\beta,\mu}(\bar p,p)$, receiving respectively contributions from diagrams of classes 1) + 2) and 2) + 3) of Fig. 4. The tensors $A^{\alpha\beta,\mu}(\bar p,p)$ and $B^{\alpha\beta,\mu}(\bar p,p)$ describe the processes where the photon couples to the charge of the light or of the heavy pseudoscalar meson,

$$
\begin{aligned}
A^{\alpha\beta,\mu}_{ab}(\bar p, p) &= -i \int \frac{d^4l}{(2\pi)^4}\, S_a(l)\, S_b(p+l) \\
&\quad \times \Big\{ S_a(l+q)\,(q+2\,l)^\mu\, \bar p^\alpha\,(p+l)^\beta + g^{\mu\alpha}\,(p+l)^\beta \Big\}\,, \\
B^{\alpha\beta,\mu}_{ab}(\bar p, p) &= +i \int \frac{d^4l}{(2\pi)^4}\, S_a(l)\, S_b(p+l) \\
&\quad \times \Big\{ S_b(\bar p+l)\,(\bar p+p+2\,l)^\mu\, \bar p^\alpha\,(\bar p+l)^\beta + g^{\mu\beta}\, l^\alpha \Big\}\,,
\end{aligned}
\tag{88}
$$

with

$$
S_a(p) = \frac{1}{p^2 - m_a^2}\,. \tag{89}
$$

We note that for technical simplicity the tensors (88) are constructed with an effective molecule vertex of the generic form $D\,\Phi\,\bar R$ as implied by the on-shell reduction technique applied in the coupled-channel computation of Section 2.1. This is the reason why diagrams of class 4) do not contribute to the expressions (88). The latter are associated with a process where the photon is emitted from a hadronic 3-point vertex involving the resonance field.

The contributions implied by the interactions involving the electromagnetic field strength tensor $F_{\mu\nu}$ are proportional to the anomalous coupling strengths e_A, e_Q, e_C of (62, 55) or the parameter e_P of (60). The terms proportional to $e_P/(f\,m_V^2)$ probe the class 2) of Fig. 4 only. Their effect is encoded into the transverse tensor $\bar A^{\alpha\beta,\mu}(\bar p, p)$,

$$
\bar A^{\alpha\beta,\mu}_{ab}(\bar p, p) = -i \int \frac{d^4l}{(2\pi)^4}\, S_a(l)\, S_b(p+l)\, \Big\{ (q\cdot l)\, g^{\mu\alpha} - l^\mu\, q^\alpha \Big\}\, (p+l)^\beta\,. \tag{90}
$$

Additional tensors $C^{\alpha\beta,\mu}(\bar p, p)$ and $\bar C^{\alpha\beta,\mu}(\bar p, p)$ describe the processes belonging to the diagrams of class 1) where the Goldstone boson, which emits the photon, is converted into a light vector meson. They are proportional to the parameter combinations $e_A\,\tilde g_T/f^2$ and $e_A\,\tilde g_E/f^2$ respectively. We introduce

$$
\begin{aligned}
C^{\alpha\beta,\mu}_{abc}(\bar p, p) &= -i \int \frac{d^4l}{(2\pi)^4}\, S_a(l)\, S_c(p+l) \\
&\quad \times 2\, q_\rho\, l_\sigma\, \epsilon^{\rho\mu\sigma}{}_\tau\, \bar p^\alpha\, (p+l)^{\bar\rho}\, \epsilon_{\bar\sigma\bar\tau\bar\rho}{}^\beta\, S_b^{\bar\sigma\bar\tau,\tau}(l+q)\,, \\
\bar C^{\alpha\beta,\mu}_{abc}(\bar p, p) &= -i \int \frac{d^4l}{(2\pi)^4}\, S_a(l)\, S_c(p+l) \\
&\quad \times 2\, q_\rho\, l_\sigma\, \epsilon^{\rho\mu\sigma}{}_\tau (p+l)_{\bar\rho}\, \epsilon^{\alpha\beta}{}_{\bar\rho\bar\sigma}\, S_b^{\bar\sigma\tau}(l+q)\,,
\end{aligned}
\tag{91}
$$

where

$$
\begin{aligned}
& S_a^{\mu\nu}(p) = p_\alpha \, S_a^{\alpha\mu,\beta\nu}(p)\, p_\beta \,, \\
& S_a^{\mu\nu,\alpha\beta}(p) = -\frac{1}{m_a^2}\, \frac{1}{p^2 - m_a^2 + i\,\epsilon} \Big[(m_a^2 - p^2)\, g_{\mu\alpha}\, g_{\nu\beta} \\
& \qquad\qquad + g_{\mu\alpha}\, p_\nu\, p_\beta - g_{\mu\beta}\, p_\nu\, p_\alpha - (\mu \leftrightarrow \nu) \Big] \,, \\
& S_a^{\mu,\beta\nu}(p) = p_\alpha \, S_a^{\alpha\mu,\beta\nu}(p)\,, \qquad\qquad S_a^{\alpha\mu,\nu}(p) = S_a^{\alpha\mu,\beta\nu}(p)\, p_\beta \,.
\end{aligned} \tag{92}
$$

Anomalous processes analogous to those described by the tensors (91) are driven by the parameters e_Q and e_C. In this case the photon is emitted by a pseudoscalar D-meson, which is converted into a vector D-meson. The contribution is included in class 3) of Fig. 4. We define the corresponding loop tensor

$$
\begin{aligned}
D^{\alpha\beta,\mu}_{abc}(\bar p, p) = +i \int \frac{d^4 l}{(2\pi)^4}\, S_a(l)\, S_c(p+l) \\
\times 2\, q_\rho\, (l+p)_\sigma\, \epsilon^{\rho\mu\sigma}{}_{\tau} \Big\{ l_{\bar\rho}\, \epsilon^{\alpha\beta\bar\rho}{}_{\bar\tau}\, S_b^{\bar\tau\tau}(\bar p + l) \, - \bar p^\alpha\, l^{\bar\rho}\, \epsilon_{\bar\sigma\bar\tau\bar\rho}{}^{\beta}\, S_b^{\bar\sigma\bar\tau,\tau}(\bar p + l) \Big\} \,.
\end{aligned} \tag{93}
$$

We emphasize that each of the tensor integrals introduced in (88, 90, 91, 93) is gauge-invariant separately, i.e. vanishes identically if contracted with q_μ. This was checked by explicit calculations.

Collecting all contributions from the $K D$ and $\eta\, D_s$ channels, we arrive at the following decay amplitude,

$$
\begin{aligned}
i\, M^{\alpha\beta,\mu}_{0^+ \to \gamma\, 1^-} = & -\frac{e\, g_P}{f}\; h^{(0+)}_{KD} \Big\{ A^{\alpha\beta,\mu}_{KD}(\bar p, p) + B^{\alpha\beta,\mu}_{KD}(\bar p, p) \Big\} \\

\end{aligned} \tag{94}
$$

where exact isospin symmetry is assumed with the coupling constant

$$
\begin{aligned}
& h^{(0+)}_{KD} = \sqrt{2}\, M_{0^+}\, g^{(0+)}_{KD} \leftrightarrow \frac{M_{0^+}^2 - M_D^2 - m_K^2}{2\, f}\, g_R \,, \\
& h^{(0+)}_{\eta D_s} = \sqrt{2}\, M_{0^+}\, g^{(0+)}_{\eta D_s} \leftrightarrow \frac{M_{0^+}^2 - M_{D_s}^2 - m_\eta^2}{2\, \sqrt{3}\, f}\, g_R \,.
\end{aligned} \tag{95}
$$

The values of the coupling constants $g^{(0+)}_{KD}$ and $g^{(0+)}_{\eta D_s}$ are given in Table 2. Note that the tensors introduced in (88, 90, 91, 93) are not antisymmetric in the indices $\alpha \leftrightarrow \beta$ as of notational convenience. While deriving the decay parameter $d_{0^+\to\gamma\,1^+}$ according to (85), the wave-function projects onto the relevant component, the application of the projection formula (87) requiring an explicit antisymmetrization.

The contributions of the $\phi\, D_s^*$ and $K^* D$ channels to the decay parameter as well as explicit results for the Passareno-Veltman reduction of the tensor integrals of (94) are detailed in Appendix D. Such contributions are proportional to g_H.

5 Radiative decay of axial-vector molecules

We derive expressions for the radiative decay amplitudes of the $D^*_{s1}(2460)$-meson corresponding to the processes $1^+ \to \gamma\, 0^-$, $1^+ \to \gamma\, 0^+$ and $1^+ \to \gamma\, 1^-$. We follow the same procedure as in the previous section for the $D^*_{s0}(2317)$ radiative decay, adjusting the tensor forms to the hadronic initial and final states.

5.1 $D^*_{s1}(2460) \to \gamma\, D_s(1968)$

The partial decay width $\Gamma_{1^+\to\gamma\,0^-}$ is expressed in terms of the transition amplitudes $M^{\mu,\alpha\beta}_{1^+\to\gamma\,0^-}$ determined by one number $d_{1^+\to\gamma\,0^-}$ as

$$\begin{aligned}
&\epsilon^\dagger_\mu(q,\lambda_q)\, M^{\mu,\alpha\beta}_{1^+\to\gamma\,0^-}\, \epsilon^{\alpha\beta}(p,\lambda_p) \\
&\qquad = d_{1^+\to\gamma\,0^-}\, \epsilon^\dagger_\mu(q,\lambda_q) \Big\{ g^{\mu\alpha}\,(\bar p\cdot q) - \bar p^\mu\, q^\alpha \Big\} \,\frac{p^\beta}{\sqrt{p^2}}\, \epsilon^{\alpha\beta}(p,\lambda_p)\,, \qquad (96)
\end{aligned}$$

implying

$$\begin{aligned}
\Gamma_{1^+\to\gamma\,0^-} &= \frac{|d_{1^+\to\gamma\,0^-}|^2}{12\pi} \left(\frac{M^2_{1^+} - M^2_{0^-}}{2\, M_{1^+}} \right)^3 , \\
d_{1^+\to\gamma\,0^-} &= \frac{1}{(p\cdot q)\, M_{1^+}} \left\{ g_{\mu\alpha} - \frac{p_\mu\, q_\alpha}{(p\cdot q)} \right\} p_\beta\, M^{\mu,\alpha\beta}\,, \qquad (97)
\end{aligned}$$

with $\bar p^2 = (p-q)^2 = M^2_{0^-}$ and $p^2 = M^2_{1^+}$. Like in (87) we exploit the fact that the decay amplitude is antisymmetric in $\alpha \leftrightarrow \beta$.

In this case again we have to consider the 5 classes of contributions depicted in Fig. 4. Any diagram is proportional to one of the three coupling constants $\tilde{g}_R, \tilde{g}_H$ or $\hat{g}_H$. In the first case, the thin and thick lines attached to the resonance vertex stand for the propagation of Goldstone bosons and vector D-mesons. In the second case, the role of thin and thick lines is interchanged in the sense that the thin lines correspond to light vector mesons, whereas the thick lines describe heavy pseudoscalar mesons. In the third case both lines represent vector mesons. The outgoing line is always a pseudoscalar D_s-meson.

We discuss the various contributions, starting with the diagrams proportional to the coupling constant $\tilde{g}_R$. There are two types of gauge-invariant combinations proportional to $e\, g_P/f$. We form two corresponding transverse tensors $A^{\mu,\alpha\beta}(\bar{p},p)$ and $B^{\mu,\alpha\beta}(\bar{p},p)$. They receive contributions from classes 1) + 2) + 4) and 2) + 3) + 4) of Fig. 4 and describe the processes where the photon couples to the charge of the light and heavy meson respectively,

$$
\begin{aligned}
A^{\mu,\alpha\beta}_{ab}(\bar{p},p) = +i \int \frac{d^4 l}{(2\pi)^4}\, S_a(l) \Big\{ & (l+\bar{p})_{\bar{\beta}}\, S_b^{\bar{\beta}\mu,\beta}(p+l)\, p^\alpha \\
& +\bar{p}_{\bar{\beta}}\, S_b^{\bar{\beta}\beta}(\bar{p}+l)\, g^{\mu\alpha} + S_a(l+q)\, \bar{p}_{\bar{\beta}}\, S_b^{\bar{\beta}\beta}(p+l)\, (q+2\,l)^\mu\, p^\alpha \Big\}\,, \\
B^{\mu,\alpha\beta}_{ab}(\bar{p},p) = +i \int \frac{d^4 l}{(2\pi)^4}\, S_a(l) \Big\{ & \bar{p}^{\bar{\alpha}}\, S_{b,\bar{\alpha}\bar{\beta}}(\bar{p}+l)\, S_b^{\mu\bar{\beta},\beta}(p+l)\, p^\alpha \\
& +\bar{p}_{\bar{\alpha}}\, S_b^{\bar{\alpha},\mu\bar{\beta}}(\bar{p}+l)\, S_{b,\bar{\beta}}{}^{\beta}(p+l)\, p^\alpha \; - l_{\bar{\beta}}\, S_b^{\mu\bar{\beta},\beta}(p+l)\, p^\alpha \\
& +\bar{p}_{\bar{\beta}}\, S_b^{\bar{\beta},\mu\beta}(\bar{p}+l)\, p^\alpha + \bar{p}_{\bar{\beta}}\, S_b^{\bar{\beta}\beta}(\bar{p}+l)\, g^{\mu\alpha} \Big\}\,. \qquad (98)
\end{aligned}
$$

The notations are the same as in (89, 92). The tensors (98) are constructed with an effective molecule vertex of the generic form $(\partial_\alpha D^{\alpha\tau})\, \Phi\, (\partial^\beta\, \bar{R}_{\beta\tau})$ as implied by the projector technique of Section 2.2. The latter is equivalent to the term proportional to $\tilde{g}_R$ in (74) (see the discussion following (75)).

The contributions driven by interactions involving the electromagnetic field strength tensor $F_{\mu\nu}$ are encoded into the transverse tensor $\bar{A}^{\mu,\alpha\beta,}(\bar{p},p)$,

$$
\bar{A}^{\mu,\alpha\beta}_{ab}(\bar{p},p) = +i \int \frac{d^4 l}{(2\pi)^4}\, S_a(l) \Big\{ (l\cdot q)\, g^\mu{}_\sigma - l^\mu\, q_\sigma \Big\}\, \bar{p}_{\bar{\beta}}\, S_b^{\bar{\beta}\sigma,\beta}(p+l)\, p^\alpha \,. (99)
$$

Additional tensors $C^{\mu,\alpha\beta}(\bar{p},p)$ and $\bar{C}^{\mu,\alpha\beta}(\bar{p},p)$ describe the processes where the Goldstone boson, which emits the photon, is converted into a light vector meson. They are proportional to the parameter combinations $e_A\, \tilde{g}_T/f^2$ and $e_A\, g_E/f^2$ respectively. We introduce

$$
\begin{aligned}
C^{\mu,\alpha\beta}_{abc}(\bar p,p) &= +2\,i\int\frac{d^4l}{(2\pi)^4}\,S_a(l)\,\bar p^{\bar\beta}\,S_b^{\sigma\tau,\tilde\alpha}(q+l)\,S_c^{\bar\alpha\beta}(p+l)\,p^\alpha \\
&\qquad\times\,\epsilon_{\sigma\tau\bar\alpha\bar\beta}\,\epsilon^{\mu}{}_{\nu\tilde\alpha\tilde\beta}\,q^\nu\,l^{\tilde\beta}\,, \\
\bar C^{\mu,\alpha\beta}_{abc}(\bar p,p) &= -2\,i\int\frac{d^4l}{(2\pi)^4}\,S_a(l)\,\bar p^{\bar\beta}\,S_b^{\bar\alpha\tilde\alpha}(q+l)\,S_c^{\sigma\tau,\beta}(p+l)\,p^\alpha \\
&\qquad\times\,\epsilon_{\sigma\tau\bar\alpha\bar\beta}\,\epsilon^{\mu}{}_{\nu\tilde\alpha\tilde\beta}\,q^\nu\,l^{\tilde\beta}\,.
\end{aligned}
\tag{100}
$$

The terms proportional to $\tilde e_C, \tilde e_Q$ are described by the tensor $D^{\mu,\alpha\beta}(\bar p,p)$. In the convention of Fig. 4 they correspond to contributions of class 3), which probe the anomalous magnetic moments of the vector D-mesons. We introduce

$$
\begin{aligned}
D^{\mu,\alpha\beta}_{ab}(\bar p,p) &= +i\int\frac{d^4l}{(2\pi)^4}\,S_a(l)\,\Big\{\bar p_{\bar\alpha}\,S_b^{\bar\alpha\mu}(\bar p+l)\,q_\tau\,S_b^{\tau\beta}(p+l)\,p^\alpha \\
&\qquad -\bar p_{\bar\alpha}\,S_b^{\bar\alpha\tau}(\bar p+l)\,q_\tau\,S_b^{\mu\beta}(p+l)\,p^\alpha\Big\}\,.
\end{aligned}
\tag{101}
$$

Each of the tensor integrals introduced in (98-101) is gauge-invariant separately.

Collecting all terms for the $K D^*$ and $\eta\, D_s^*$ channels, we arrive at the decay amplitude

$$
\begin{aligned}
M^{\mu,\alpha\beta}_{1^+\to\gamma\,0^-} &= -\frac{e\,g_P}{f}\,h^{(1+)}_{KD^*}\left\{A^{\mu,\alpha\beta}_{KD^*}(\bar p,p)+B^{\mu,\alpha\beta}_{KD^*}(\bar p,p)\right\} \\
&\quad -\frac{e_P}{f\,m_V^2}\,h^{(1+)}_{KD^*}\,\bar A^{\mu,\alpha\beta}_{KD^*}(\bar p,p)-\frac{2}{\sqrt3}\,\frac{e\,g_P}{f}\,h^{(1+)}_{\eta D_s^*}\,B^{\mu,\alpha\beta}_{\eta D_s^*}(\bar p,p) \\
&\quad +\frac{e_A}{48\,f^2\,m_V}\,h^{(1+)}_{KD^*}\left\{\tilde g_T\,C^{\mu,\alpha\beta}_{KK^*D^*}(\bar p,p)+g_E\,\bar C^{\mu,\alpha\beta}_{KK^*D^*}(\bar p,p)\right\} \\
&\quad +\frac{e_A}{\sqrt3\,12\,f^2\,m_V}\,h^{(1+)}_{\eta D_s^*}\left\{\tilde g_T\,C^{\mu,\alpha\beta}_{\eta\phi D_s^*}(\bar p,p)+g_E\,\bar C^{\mu,\alpha\beta}_{\eta\phi D_s^*}(\bar p,p)\right\} \\
&\quad -\frac{g_P}{f\,M_V^2}\Big\{\frac{2}{\sqrt3}\,\frac{3\,\tilde e_C+\tilde e_Q-3\,e}{3}\,h^{(1+)}_{\eta D_s^*}\,D^{\mu,\alpha\beta}_{\eta D_s^*}(\bar p,p) \\
&\qquad\qquad +\frac{6\,\tilde e_C-\tilde e_Q-3\,e}{3}\,h^{(1+)}_{KD^*}\,D^{\mu,\alpha\beta}_{KD^*}(\bar p,p)\Big\}\,,
\end{aligned}
\tag{102}
$$

where

$$
\begin{aligned}
h^{(1+)}_{KD^*} &= \sqrt2\,\frac{g^{(1+)}_{KD^*}}{M_{D^*}}\leftrightarrow\frac{M_{1^+}^2-M_{D^*}^2-m_K^2}{2\,f\,M_{1^+}^2}\,\tilde g_R\,, \\
h^{(1+)}_{\eta D_s^*} &= \sqrt2\,\frac{g^{(1+)}_{\eta D_s^*}}{M_{D_s^*}}\leftrightarrow\frac{M_{1^+}^2-M_{D_s^*}^2-m_\eta^2}{2\,\sqrt3\,f\,M_{1^+}^2}\,\tilde g_R\,.
\end{aligned}
\tag{103}
$$

The values of the coupling constants $g^{(1+)}_{KD}$ and $g^{(1+)}_{\eta D_s}$ are given in Table 2. We reemphasize that the application of the projection formula (97) requires an antisymmetrization of the tensors (98-101).

We turn to the contributions implied by the channels involving the K^* or ϕ meson. Such terms are proportional to the coupling constants $\tilde{g}_H$ or $\hat{g}_H$ introduced in (80).

While the terms proportional to $\hat{g}_H$ are deferred to Appendix E, we detail those proportional to $\tilde{g}_H$ here. The former encode the physics of the $K^* D^*$ and $\phi\, D^*$ channels. Appendix E provides in addition explicit results for the Passareno-Veltman reduction of the tensor integrals (98-101, 104). The terms proportional to $\tilde{g}_H$ are evaluated like those proportional to g_R. Formally the role of light and heavy intermediate lines in Fig. 4 is interchanged but the result involves the same tensor integrals as (98-101). Additional tensors are required to describe the effects of the terms proportional to $e_V \neq 0$ or $e_E \neq 0$ introduced in (66). The latter give rise to contributions of class 2) in Fig. 4. They are analogous to the contributions proportional to e_P in (102). We form the gauge-invariant tensors $\bar{B}^{\mu,\alpha\beta}(\bar{p},p)$ and $\tilde{B}^{\mu,\alpha\beta}(\bar{p},p)$,

$$\begin{aligned}
\bar{B}^{\mu,\alpha\beta}_{ab}(\bar{p},p) &= -i \int \frac{d^4 l}{(2\pi)^4}\, S_a(l)\, S_b^{\tau\beta}(p+l)\, p^\alpha \\
&\qquad \times\Big((l\cdot q)\, g^\mu{}_\tau - l^\mu\, q_\tau - (\bar{p}\cdot q)\, g^\mu{}_\tau + \bar{p}^\mu\, q_\tau \Big)\,, \\
\tilde{B}^{\mu,\alpha\beta}_{ab}(\bar{p},p) &= -2\, i \int \frac{d^4 l}{(2\pi)^4}\, S_a(l)\, q_\tau\, S_b^{\tau\mu,\beta}(p+l)\, p^\alpha\, (\bar{p}\cdot l)\,. \qquad (104)
\end{aligned}$$

We collect the contributions of the $K^* D$ and $\phi\, D_s$ channels to the decay amplitude

$$\begin{aligned}
M^{\mu,\alpha\beta}_{1^+\to\gamma 0^-} =& -\frac{e\, g_V\, \tilde{g}_H}{f^2}\, \Big\{ A^{\mu,\alpha\beta}_{DK^*}(\bar{p},p) + B^{\mu,\alpha\beta}_{DK^*}(\bar{p},p) + A^{\mu,\alpha\beta}_{D_s\phi}(\bar{p},p) \Big\} \\
& - \frac{e_V\, \tilde{g}_H}{2\, f^2\, m_V^2}\, \bar{B}^{\mu,\alpha\beta}_{DK^*}(\bar{p},p) + \frac{e_E\, \tilde{g}_H}{3\, f^2\, m_V^2}\, \tilde{B}^{\mu,\alpha\beta}_{DK^*}(\bar{p},p) + \frac{2\, e_E\, \tilde{g}_H}{3\, f^2\, m_V^2}\, \tilde{B}^{\mu,\alpha\beta}_{D_s\phi}(\bar{p},p) \\
& + \frac{(e_C + e_Q/6)\, \tilde{g}_H}{4\, f^2\, M_V^2}\, \Big\{ g_E\, C^{\mu,\alpha\beta}_{DD^*K^*}(\bar{p},p) + \tilde{g}_T\, \bar{C}^{\mu,\alpha\beta}_{DD^*K^*}(\bar{p},p) \Big\} \\
& + \frac{(e_C - e_Q/3)\, \tilde{g}_H}{8\, f^2\, M_V^2}\, \Big\{ g_E\, C^{\mu,\alpha\beta}_{D_s D_s^*\phi}(\bar{p},p) + \tilde{g}_T\, \bar{C}^{\mu,\alpha\beta}_{D_s D_s^*\phi}(\bar{p},p) \Big\}\,, \qquad (105)
\end{aligned}$$

in terms of the tensor integrals of (98-100, 104). There is no term involving the tensor (101) since we neglect the effect of the anomalous magnetic moment of the light vector mesons.

5.2 $D^*_{s1}(2460) \to \gamma\, D^*_{s0}(2317)$

The partial decay width $\Gamma_{1^+\to\gamma\,0^+}$ is expressed in terms of the transition amplitudes $M^{\mu,\alpha\beta}_{1^+\to\gamma\,0^+}$ determined by the number $d_{1^+\to\gamma\,0^+}$ as

$$\begin{aligned}
&\epsilon^\dagger_\mu(q,\lambda_q)\, M^{\mu,\alpha\beta}_{1^+\to\gamma\,0^+}\, \epsilon^{\alpha\beta}(p,\lambda_p) \\
&\qquad = d_{1^+\to\gamma\,0^+}\, \epsilon^\dagger_\mu(q,\lambda_q)\, q_\tau\, \epsilon^{\mu\tau}{}_{\sigma\alpha}\, p^\sigma\, \frac{p^\beta}{\sqrt{p^2}}\, \epsilon^{\alpha\beta}(p,\lambda_p)\,,
\end{aligned} \tag{106}$$

implying

$$\begin{aligned}
\Gamma_{1^+\to\gamma\,0^+} &= \frac{|d_{1^+\to\gamma\,0^+}|^2}{12\pi}\left(\frac{M^2_{1^+}-M^2_{0^+}}{2\,M_{1^+}}\right)^3 , \\
d_{1^+\to\gamma\,0^+} &= \frac{-1}{(p\cdot q)^2\, M_{1^+}}\, q^\tau\, \epsilon_{\mu\tau\sigma\alpha}\, p^\sigma\, p_\beta\, M^{\mu,\alpha\beta}\,,
\end{aligned} \tag{107}$$

with $\bar p^2 = (p-q)^2 = M^2_{0^+}$ and $p^2 = M^2_{1^+}$.

There are 4 classes of contributions. They are depicted in Fig. 7. Like in Fig. 4 the solid lines stand for the propagation of pseudoscalar or vector mesons. The thick lines are used for the heavy mesons, the thin ones for the light mesons. The solid and dashed double lines represent the molecule of the initial and final state respectively. Any diagram is proportional to one of the four products of coupling constants $g_R\,\tilde g_R$, $g_R\,\tilde g_H$, $g_H\,\tilde g_R$ or $g_H\,\tilde g_H$. We discuss the four possibilities case by case.

In the first two cases (terms proportional to $g_R\,\tilde g_R$ or $g_R\,\tilde g_H$), the thin and thick lines attached to the final molecule vertex represent the propagation of pseudoscalar light and heavy mesons. There is only one generic tensor $A^{\mu,\alpha\beta}_{+,abc}(\bar p, p)$ describing these processes. They are of class 1) or 3) in the convention of Fig. 7. The contributions probe anomalous electromagnetic vertices proportional

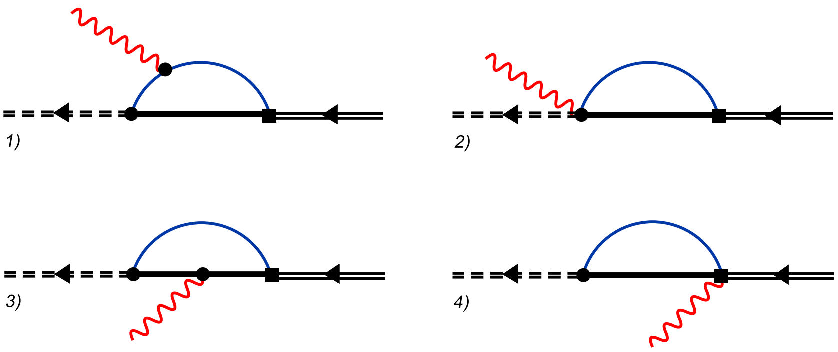

Fig. 7. Diagrams contributing to the process $1^+ \to \gamma\, 0^+$.

to e_A or e_C and e_Q. We define

$$A^{\mu,\alpha\beta}_{+,abc}(\bar{p},p) = -2\,i\,q_\tau\,\epsilon^{\mu\tau}{}_{\sigma\rho}\int\frac{d^4l}{(2\pi)^4}\,S_a(l)\,S_b(l+\bar{p})\,(l+\bar{p})^\rho\,S_c^{\sigma\beta}(l+p)\,p^\alpha\,. \tag{108}$$

For the terms proportional to $g_H\,\tilde{g}_R$, there is a class 1) contribution only, with thick lines describing the propagation of vector mesons. The thin line changes from a pseudoscalar to a vector line at the photon vertex. The contributions are proportional to the anomalous coupling constant e_A. We introduce the corresponding gauge-invariant tensor

$$D^{\mu,\alpha\beta}_{+,abc}(\bar{p},p) = -2\,i\,q_\nu\,\epsilon^{\mu\nu}{}_{\sigma\tau}\,g_{\bar{\kappa}\kappa}\int\frac{d^4l}{(2\pi)^4}\,l^\tau\,p^\alpha\,S_a(l)\,S_b^{\bar{\kappa}\sigma}(l+q)\,S_c^{\kappa\beta}(p+l)\,. \tag{109}$$

For the contributions proportional to $g_H\,\tilde{g}_H$, there are two types of gauge-invariant combinations. We form two transverse tensors $B^{\mu,\alpha\beta}_{+}(\bar{p},p)$ and $C^{\mu,\alpha\beta}_{+}(\bar{p},p)$ receiving contributions from classes 2) + 3) + 4) and 1) + 2) + 4) of Fig. 7 respectively. The tensors $B^{\mu,\alpha\beta}_{+}(\bar{p},p)$ and $C^{\mu,\alpha\beta}_{+}(\bar{p},p)$ describe the processes where the photon couples to the charge of the heavy and light mesons. We introduce the gauge-invariant tensors

$$\begin{aligned}
B^{\mu,\alpha\beta}_{+,ab}(\bar{p},p) &= -\,i\,\epsilon_{\tilde{\alpha}\tilde{\beta}\sigma}{}^{\beta}\,g_{\bar{\rho}\rho}\int\frac{d^4l}{(2\pi)^4}\,S_a^{\bar{\rho}\sigma}(l)\,\Bigg\{g^{\mu\alpha}\,S_b^{\rho,\tilde{\alpha}\tilde{\beta}}(l+\bar{p}) \\
&\qquad + p^\alpha\,S_b^{\mu\rho,\tilde{\alpha}\tilde{\beta}}(l+p) + g_{\bar{\kappa}\kappa}\,p^\alpha\,\Big\{S_b^{\rho\bar{\kappa}}(\bar{p}+l)\,S_b^{\mu\kappa,\tilde{\alpha}\tilde{\beta}}(p+l) \\
&\qquad\qquad + S_b^{\bar{\rho},\mu\bar{\kappa}}(\bar{p}+l)\,S_b^{\kappa,\tilde{\alpha}\tilde{\beta}}(p+l)\Big\}\Bigg\}\,, \\
C^{\mu,\alpha\beta}_{+,ab}(\bar{p},p) &= +\,i\,\epsilon_{\tilde{\alpha}\tilde{\beta}\tau}{}^{\beta}\,g_{\bar{\rho}\rho}\int\frac{d^4l}{(2\pi)^4}\,S_a^{\bar{\rho},\tilde{\alpha}\tilde{\beta}}(l)\,\Bigg\{p^\alpha\,S_b^{\rho,\mu\tau}(l+\bar{p}) \\
&\qquad + g^{\mu\alpha}\,S_b^{\rho\tau}(l+\bar{p}) + p^\alpha\,S_b^{\mu\rho,\tau}(l+p) \\
&\qquad + g_{\bar{\kappa}\kappa}\,p^\alpha\,\Big\{S_b^{\rho\bar{\kappa}}(\bar{p}+l)\,S_b^{\mu\kappa,\tau}(p+l) + S_b^{\bar{\rho},\mu\bar{\kappa}}(\bar{p}+l)\,S_b^{\kappa\tau}(p+l)\Big\}\Bigg\}\,.
\end{aligned} \tag{110}$$

The tensor integrals introduced in (108-110) are gauge-invariant separately. Collecting all terms we arrive at the decay amplitude

$$M^{\mu,\alpha\beta}_{1^+\to\gamma 0^+} = \frac{e_C + e_Q/6}{2\,M_V^2}\,h^{(0^+)}_{KD}\,h^{(1^+)}_{KD^*}\,A^{\mu,\alpha\beta}_{+,KDD^*}(\bar{p},p)$$

$$
\begin{aligned}
&+\frac{e_C - e_Q/3}{2\,M_V^2}\, h^{(0^+)}_{\eta D_s}\, h^{(1^+)}_{\eta D_s^*}\, A^{\mu,\alpha\beta}_{+,\eta D_s D_s^*}(\bar p, p) \\
&+\frac{e_A}{6\sqrt{3}\, f^2\, m_V}\left\{\tilde g_H\, h^{(0^+)}_{\eta D_s}\, A^{\mu,\alpha\beta}_{+,D_s\eta\phi}(\bar p, p) + g_H\, h^{(1^+)}_{\eta D_s}\, D^{\mu,\alpha\beta}_{+,\phi\eta D_s^*}(\bar p, p)\right\} \\
&+\frac{e_A}{24\, f^2\, m_V}\left\{\tilde g_H\, h^{(0^+)}_{KD}\, A^{\mu,\alpha\beta}_{+,DKK^*}(\bar p, p) + g_H\, h^{(1^+)}_{KD}\, D^{\mu,\alpha\beta}_{+,K^*KD}(\bar p, p)\right\} \\
&+e\,\frac{\hat g_H\, g_H}{4\, f^2}\left\{B^{\mu,\alpha\beta}_{+,\phi D_s^*}(\bar p, p) + B^{\mu,\alpha\beta}_{+,K^* D^*}(\bar p, p) + C^{\mu,\alpha\beta}_{+,D^* K^*}(\bar p, p)\right\} \\
&+\frac{g_H\, \tilde g_H}{2\, f^2}\left\{\frac{e_C + e_Q/6}{2\,M_V^2}\, D^{\mu,\alpha\beta}_{+,DD^*K^*}(\bar p, p) + \frac{e_C - e_Q/3}{2\,M_V^2}\, D^{\mu,\alpha\beta}_{+,D_s D_s^*\phi}(\bar p, p)\right\} \qquad (111)
\end{aligned}
$$

where the coupling constants h_{KD} and $h_{\eta D_s}$ are specified in (95, 103) in terms of the values given in Table 2. Appendix F provides the results of a Passareno-Veltman reduction of the tensor integrals (108-110).

5.3 $D_{s1}^*(2460) \to \gamma\, D_s^*(2112)$

This radiative decay mode is described by a rank-five transition tensor $M^{\bar\alpha\bar\beta,\mu,\alpha\beta}_{1^+\to\gamma\, 1^-}$. The decay amplitude has a slightly more complicated structure than those displayed in (85, 106). It is characterized by two scalar decay parameters as the decay may go via an s-wave or a d-wave transition. Separating these two transitions is an original and interesting feature of our work leading to angular distributions. We write

$$
\begin{aligned}
&\epsilon^\dagger_\mu(q,\lambda_q)\, \epsilon^\dagger_{\bar\alpha\bar\beta}(\bar p,\lambda_{\bar p})\, M^{\bar\alpha\bar\beta,\mu,\alpha\beta}_{1^+\to\gamma\, 1^-}\, \epsilon_{\alpha\beta}(p,\lambda_p) = \epsilon^\dagger_\mu(q,\lambda_q)\, \frac{-i\,\bar p^{\bar\beta}\, \epsilon^\dagger_{\bar\alpha\bar\beta}(\bar p,\lambda_{\bar p})}{\sqrt{\bar p^2}} \\
&\times q_\tau\, \epsilon^{\mu\tau\bar\alpha\sigma}\left\{d^{(1)}_{1^+\to\gamma\, 1^-}\, \frac{q^\alpha\, p_\sigma}{(q\cdot p)} + d^{(2)}_{1^+\to\gamma\, 1^-}\left(g^\alpha_{\ \sigma} - \frac{q^\alpha\, p_\sigma}{(q\cdot p)}\right)\right\}\frac{p^\beta\, \epsilon_{\alpha\beta}(p,\lambda_p)}{\sqrt{p^2}}\,. \qquad (112)
\end{aligned}
$$

To verify that there are indeed only two independent decay parameters requires using the identity

$$
g_{\sigma\tau}\epsilon_{\alpha\beta\gamma\delta} = g_{\alpha\tau}\epsilon_{\sigma\beta\gamma\delta} + g_{\beta\tau}\epsilon_{\alpha\sigma\gamma\delta} + g_{\gamma\tau}\epsilon_{\alpha\beta\sigma\delta} + g_{\delta\tau}\epsilon_{\alpha\beta\gamma\sigma}\,. \qquad (113)
$$

We obtain for the decay width

$$
\Gamma_{1^+\to\gamma\, 1^-} = \frac{1}{12\,\pi}\left\{\left|\frac{d^{(1)}_{1^+\to\gamma\, 1^-}}{M_{1^+}}\right|^2 + \left|\frac{d^{(2)}_{1^+\to\gamma\, 1^-}}{M_{1^-}}\right|^2\right\}\left(\frac{M_{1^+}^2 - M_{1^-}^2}{2\,M_{1^+}}\right)^3, \qquad (114)
$$

with $\bar p^2 = M^2_{1^-}$ and $p^2 = M^2_{1^+}$. As indicated by (113), it is quite cumbersome to extract the two decay parameters from a given amplitude. Fortunately, this task can be streamlined considerably by the projection identities,

$$
\begin{aligned}
d^{(1)}_{1^+\to\gamma\,1^-} &= \frac{+i\,16\,M_{1^+}}{M_{1^-}\,(M^2_{1^+}-M^2_{1^-})^3}\,p^\sigma\,q^\tau\,\epsilon_{\sigma\tau\bar\alpha\mu}\,\bar p_{\bar\beta}\,M^{\bar\alpha\bar\beta,\mu,\alpha\beta}_{1^+\to\gamma\,1^-}\,q_\alpha\,p_\beta\,,\\
d^{(2)}_{1^+\to\gamma\,1^-} &= \frac{+i\,16\,M_{1^-}}{M_{1^+}\,(M^2_{1^+}-M^2_{1^-})^3}\,p^\sigma\,q^\tau\,\epsilon_{\sigma\tau\mu\alpha}\,q_{\bar\alpha}\,\bar p_{\bar\beta}\,M^{\bar\alpha\bar\beta,\mu,\alpha\beta}_{1^+\to\gamma\,1^-}\,p_\beta\,,
\end{aligned}
\tag{115}
$$

resulting from the antisymmetry and transversality of the decay amplitude.

We consider the 5 classes of contributions depicted in Fig. 4. Any diagram is proportional to one of the three coupling constants $\tilde g_R, \tilde g_H$ or $\hat g_H$. In the first case the thin and thick lines attached to the resonance vertex stand for the propagation of Goldstone bosons and vector D-mesons. In the second case the thin lines correspond to light vector mesons whereas the thick lines describe heavy pseudoscalar mesons. In the third case both lines stand for vector mesons. The outgoing line is always a vector D^*_s-meson.

We discuss the various contributions starting with diagrams proportional to the coupling constant $\tilde g_R$. There are two types of gauge-invariant combinations proportional to $e\,\tilde g_P/f$. We form the two corresponding transverse tensors $A^{\bar\alpha\bar\beta,\mu,\alpha\beta}_{+}(\bar p,p)$ and $B^{\bar\alpha\bar\beta,\mu,\alpha\beta}_{+}(\bar p,p)$, receiving contributions from classes 1) + 2) + 4) + 5) and 2) + 3) + 4) + 5) of Fig. 4 respectively. The tensors $A^{\bar\alpha\bar\beta,\mu,\alpha\beta}_{+}(\bar p,p)$ and $B^{\bar\alpha\bar\beta,\mu,\alpha\beta}_{+}(\bar p,p)$ describe the processes where the photon couples to the charge of the light and heavy mesons,

$$
\begin{aligned}
A^{\bar\alpha\bar\beta,\mu,\alpha\beta}_{\pm,ab}(\bar p,p) = -i\int\frac{d^4l}{(2\pi)^4}\,S_a(l)\,\Big\{&\epsilon^{\bar\alpha\bar\beta}{}_{\sigma\tau}\,\Big[-g^{\mu\sigma}\,S^{\tau\beta}_b(p+l)\,p^\alpha\\
&+l^\sigma\,S^{\tau\beta}_b(\bar p+l)\,g^{\mu\alpha}\,+(l+q)^\sigma\,S_a(l+q)\,S^{\tau\beta}_b(p+l)\,(q+2\,l)^\mu\,p^\alpha\Big]\\
&+\epsilon^{\tilde\alpha\tilde\beta}{}_{\sigma\tau}\,\bar p^{\bar\alpha}\,S^{\mu\bar\beta}_{\bar p,\ \ \tilde\alpha\tilde\beta}(p)\,l^\sigma\,S^{\tau\beta}_b(p+l)\,p^\alpha\mp\epsilon_{\sigma\tau}{}^{\rho\bar\beta}\,\Big[-g^\mu{}_\rho\,\bar p^{\bar\alpha}\,S^{\sigma\tau,\beta}_b(p+l)\,p^\alpha\\
&+l_\rho\,g^{\mu\bar\alpha}\,S^{\sigma\tau,\beta}_b(p+l)\,p^\alpha+\bar p^{\bar\alpha}\,l_\rho\,S^{\sigma\tau,\beta}_b(\bar p+l)\,\ g^{\mu\alpha}\\
&+\bar p^{\bar\alpha}\,(l+q)_\rho\,S_a(l+q)\,S^{\sigma\tau,\beta}_b(p+l)\,(q+2\,l)^\mu\,p^\alpha\Big]\Big\}\,,\\
B^{\bar\alpha\bar\beta,\mu,\alpha\beta}_{\pm,ab}(\bar p,p) = -i\int\frac{d^4l}{(2\pi)^4}\,S_a(l)\,\Big\{&\epsilon^{\bar\alpha\bar\beta}{}_{\sigma\tau}\,\Big[+l_\sigma\,S^{\mu\tau,\beta}_b(p+l)\,p^\alpha\\
&+l^\sigma\,S^{\tau\beta}_b(\bar p+l)\,g^{\mu\alpha}+l^\sigma\,S^{\tau,\mu\beta}_b(\bar p+l)\,p^\alpha\\
&+l^\sigma\,g_{\bar\kappa\kappa}\,\Big\{S^{\tau,\mu\bar\kappa}_b(\bar p+l)\,S^{\kappa\beta}_b(p+l)+S^{\tau\bar\kappa}_b(\bar p+l)\,S^{\mu\kappa,\beta}_b(p+l)\Big\}\,p^\alpha\Big]\\
&+\epsilon^{\tilde\alpha\tilde\beta}{}_{\sigma\tau}\,\bar p^{\bar\alpha}\,S^{\mu\bar\beta}_{\bar p,\ \ \tilde\alpha\tilde\beta}(p)\,l^\sigma\,S^{\tau\beta}_b(p+l)\,p^\alpha\mp\epsilon_{\sigma\tau}{}^{\rho\bar\beta}\,\Big[+l_\rho\,g^{\mu\bar\alpha}\,S^{\sigma\tau,\beta}_b(p+l)\,p^\alpha
\end{aligned}
$$

$$
\begin{aligned}
&+ l_\rho\, \bar p^{\bar\alpha}\, S_b^{\sigma\tau,\beta}(\bar p + l)\, g^{\mu\alpha} + l_\rho\, \bar p^{\bar\alpha}\, S_b^{\sigma\tau,\mu\beta}(\bar p + l)\, p^\alpha \\
&+ l_\rho\, \bar p^{\bar\alpha}\, g_{\bar\kappa\kappa} \Big\{ S_b^{\sigma\tau,\bar\kappa}(\bar p + l)\, S_b^{\mu\kappa,\beta}(p+l) + S_b^{\sigma\tau,\mu\bar\kappa}(\bar p + l)\, S_b^{\kappa\beta}(p+l) \Big\}\, p^\alpha \Big] \Bigg\} .
\end{aligned}
\tag{116}
$$

In the tensors $A_{\pm,ab}^{\bar\alpha\bar\beta,\mu,\alpha\beta}$ and $B_{\pm,ab}^{\bar\alpha\bar\beta,\mu,\alpha\beta}$ there are contributions where the photon couples to the final vector particle. In the convention of Fig. 4, these are diagrams of class 5). They give rise to terms proportional to $S_{\bar p}^{\bar\alpha\bar\beta,\alpha\beta}(p)$, with $m_{\bar p}^2 = \bar p^2$. Such contributions are not at odds with parity conservation since the tensor field carries spin one quanta with both parities. Analogous terms where the photon couples to the initial vector meson do not arise due to parity conservation. Since the resonance field couples always with $(\partial_\tau R^{\tau\alpha})$, only the positive parity component is accessible.

The contributions induced by interactions involving the electromagnetic field strength tensor $F_{\mu\nu}$ are proportional to the anomalous coupling strengths e_A, e_Q, e_C, $\tilde e_Q$ and $\tilde e_C$ of (62, 55, 57) or the parameter $\tilde e_P$ of (60). The terms proportional to $\tilde e_P/(f\, m_V^2)$ probe the class 2) of Fig. 4 only. Their effect is encoded into the transverse tensor $\bar A_{+}^{\bar\alpha\bar\beta,\mu,\alpha\beta,}(\bar p, p)$. The tensor $\bar B_{ab}^{\bar\alpha\bar\beta,\mu,\alpha\beta}(\bar p, p)$ is associated with contributions probing the anomalous magnetic moment of the D mesons, which are proportional to $\tilde e_C$ and $\tilde e_Q$,

$$
\begin{aligned}
\bar A_{\pm,ab}^{\bar\alpha\bar\beta,\mu,\alpha\beta}(\bar p, p) = -i \int \frac{d^4 l}{(2\pi)^4}\, S_a(l) \Bigg\{ &\epsilon^{\bar\alpha\bar\beta}{}_{\sigma\tau} \Big(l^\mu\, q^\sigma - (l\cdot q)\, g^{\mu\sigma} \Big)\, S_b^{\tau\beta}(p+l) \\
&\mp \epsilon_{\sigma\tau}{}^{\rho\bar\beta} \Big(l^\mu\, q_\rho - (l\cdot q)\, g^\mu{}_\rho \Big)\, \bar p^{\bar\alpha}\, S_b^{\sigma\tau,\beta}(p+l) \Bigg\}\, p^\alpha ,
\end{aligned}
\tag{117}
$$

$$
\begin{aligned}
\bar B_{ab}^{\bar\alpha\bar\beta,\mu,\alpha\beta}(\bar p, p) = +i \int \frac{d^4 l}{(2\pi)^4}\, S_a(l) \Bigg\{ &\epsilon^{\bar\alpha\bar\beta}{}_{\sigma\tau} \Big[l^\sigma\, q_\kappa \Big\{ S_b^{\tau\kappa}(\bar p + l)\, S_b^{\mu\beta}(p+l) \\
&- S_b^{\tau\mu}(\bar p + l)\, S_b^{\kappa\beta}(p+l) \Big\}\, p^\alpha \Big] - \epsilon_{\sigma\tau}{}^{\rho\bar\beta} \Big[l_\rho\, q_\kappa\, \bar p^{\bar\alpha} \Big\{ S_b^{\sigma\tau,\kappa}(\bar p + l)\, S_b^{\mu\beta}(p+l) \\
&- S_b^{\sigma\tau,\mu}(\bar p + l)\, S_b^{\kappa\beta}(p+l) \Big\}\, p^\alpha \Big] \Bigg\} .
\end{aligned}
\tag{118}
$$

The additional tensors $C_{+}^{\bar\alpha\bar\beta,\mu,\alpha\beta}(\bar p, p)$ and $\bar C^{\bar\alpha\bar\beta,\mu,\alpha\beta}(\bar p, p)$ describe the processes where the Goldstone boson, which emits the photon, is converted into a light vector meson as included in class 1). They are proportional to the parameter combinations $e_A\, \tilde g_V/f^2$ and $e_A\, g_T/f^2$ respectively. We define

$$
C_{\pm,abc}^{\bar\alpha\bar\beta,\mu,\alpha\beta}(\bar p, p) = +2\, i \int \frac{d^4 l}{(2\pi)^4}\, S_a(l)\, q_\nu\, \epsilon^{\mu\nu}{}_{\sigma\tau}\, l^\tau \Bigg\{ S_b^{\bar\alpha\sigma}(l+q)\, S_c^{\bar\beta\beta}(l+p)\, p^\alpha
$$

$$\pm\, \bar{p}^{\bar{\alpha}}\, g_{\bar{\kappa}\kappa}\, S_b^{\bar{\kappa}\sigma}(l+q)\, S_c^{\kappa\bar{\beta},\beta}(l+p)\, p^{\alpha} \Bigg\}, \tag{119}$$

$$\bar{C}_{abc}^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}(\bar{p},p) = +2\, i \int \frac{d^4 l}{(2\pi)^4}\, S_a(l)\, q_\nu\, \epsilon^{\mu\nu}{}_{\sigma\tau}\, l^{\tau}\, \bar{p}^{\bar{\alpha}}$$
$$\times\, g_{\bar{\kappa}\kappa}\, S_b^{\bar{\kappa}\bar{\beta},\sigma}(l+q)\, S_c^{\kappa\beta}(l+p)\, p^{\alpha}\ . \tag{120}$$

Anomalous processes analogous to those described by the tensors (119) are driven by e_Q and e_C. In this case the photon is emitted by a pseudoscalar D-meson, which is converted into a vector D-meson. The contribution is included in class 3) of Fig. 4. We introduce the corresponding loop tensor

$$D_{abc}^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}(\bar{p},p) = +2\, i \int \frac{d^4 l}{(2\pi)^4}\, S_a(l)\, S_b(l+\bar{p})$$
$$\times l^{\bar{\alpha}}\, \bar{p}^{\bar{\beta}}\, q_\tau\, \epsilon^{\mu\tau}{}_{\rho\sigma}\, (l+\bar{p})^{\sigma}\, S_c^{\rho\beta}(l+p)\, p^{\alpha}\, . \tag{121}$$

The tensor integrals introduced in (116, 117, 119, 121) are again gauge-invariant separately.

Summing all terms, we get the decay amplitude

$$\begin{aligned}
-i\, M^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{1^+\to\gamma\, 1^-} = {} & \frac{e\, \tilde{g}_P}{4\, f}\, h^{(1+)}_{KD^*} \left\{ A^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{+,KD^*}(\bar{p},p) + B^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{+,KD^*}(\bar{p},p) \right\} \\
& + \frac{\tilde{e}_P}{4\, f\, m_V^2}\, h^{(1+)}_{KD^*}\, \bar{A}^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{+,KD^*}(\bar{p},p) + \frac{2}{\sqrt{3}}\, \frac{e\, \tilde{g}_P}{4\, f}\, h^{(1+)}_{\eta D_s^*}\, B^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{+,\eta D_s^*}(\bar{p},p) \\
& + \frac{\tilde{g}_P}{4\, f\, M_V^2} \Big\{ \frac{2}{\sqrt{3}}\, \frac{3\, \tilde{e}_C + \tilde{e}_Q - 3\, e}{3}\, h^{(1+)}_{\eta D_s^*}\, \bar{B}^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{\eta D_s^*}(\bar{p},p) \\
& \qquad\qquad + \frac{6\, \tilde{e}_C - \tilde{e}_Q - 3\, e}{3}\, h^{(1+)}_{KD^*}\, \bar{B}^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{KD^*}(\bar{p},p) \Big\} \\
& - \frac{e_A}{24\, f^2\, m_V}\, h^{(1+)}_{KD^*} \left\{ \tilde{g}_V\, C^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{+,KK^*D^*}(\bar{p},p) + g_T\, \bar{C}^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{KK^*D^*}(\bar{p},p) \right\} \\
& - \frac{e_A}{\sqrt{3}\, 6\, f^2\, m_V}\, h^{(1+)}_{\eta D_s^*} \left\{ \tilde{g}_V\, C^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{+,\eta\phi D_s^*}(\bar{p},p) + g_T\, \bar{C}^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{\eta\phi D_s^*}(\bar{p},p) \right\} \\
& - \frac{g_P}{f\, M_V^2} \Big\{ \frac{2}{\sqrt{3}}\, \frac{3\, e_C - e_Q}{6}\, h^{(1+)}_{\eta D_s^*}\, D^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{\eta D_s D_s^*}(\bar{p},p) \\
& \qquad\qquad + \frac{6\, e_C + e_Q}{6}\, h^{(1+)}_{KD^*}\, D^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{KDD^*}(\bar{p},p) \Big\}\, .
\end{aligned} \tag{122}$$

We turn to the contributions induced by the coupling constants $\tilde{g}_H$ and $\hat{g}_H$ introduced in (80). The terms proportional to $\hat{g}_H$ are deferred to Appendix G. We discuss those proportional to $\tilde{g}_H$. The former are expected to be more relevant than the latter due to phase space. Appendix G provides in addition explicit results for the Passareno-Veltman reduction of the tensor integrals (116-121, 123).

The evaluation of terms proportional to $\tilde{g}_H$ is similar to those proportional to g_R. Formally the role of light and heavy intermediate lines in Fig. 4 is interchanged so that the tensor integrals formed in (116-121) will occur again. Additional tensors are required to describe the implications of $\tilde{e}_T \neq 0$ as introduced in (66). The latter give rise to contributions of class 2) in Fig. 4. They are analogous to the contributions proportional to $\tilde{e}_P$ in (111). We form the gauge-invariant tensor $\tilde{B}^{\mu,\alpha\beta}(\bar{p},p)$

$$\begin{aligned}\tilde{B}^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{ab}(\bar{p},p) = +i \int \frac{d^4 l}{(2\pi)^4}\, S_a(l)\, \bar{p}^{\bar{\alpha}}\, l_\rho\, \epsilon^{\rho\bar{\beta}}{}_{\bar{\sigma}\tau}\, S_b^{\sigma\tau,\beta}(p+l) \\ \times \Big(g^{\mu}{}_{\sigma}\, q^{\bar{\sigma}} - g^{\mu\bar{\sigma}}\, q^{\sigma}\Big)\, p^{\alpha}\,. \end{aligned} \tag{123}$$

The contributions proportional to $\tilde{g}_H$ are

$$\begin{aligned} -i\, M^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{1^+\to\gamma\,1^-} &= -\frac{e\,(g_E+\tilde{g}_T)\,\tilde{g}_H}{8\,f^2}\,\Big\{A^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{+,DK^*}(\bar{p},p) + B^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{+,DK^*}(\bar{p},p)\Big\} \\ &\quad - \frac{e\,(g_E-\tilde{g}_T)\,\tilde{g}_H}{8\,f^2}\,\Big\{A^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{-,DK^*}(\bar{p},p) + B^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{-,DK^*}(\bar{p},p)\Big\} \\ &\quad - \frac{\tilde{e}_T\,\tilde{g}_H}{4\,f^2\,m_V^2}\,\tilde{B}^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{DK^*}(\bar{p},p) \\ &\quad - \frac{e\,\tilde{g}_H}{8\,f^2}\,\Big\{(g_E+\tilde{g}_T)\,A^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{+,D_s\phi}(\bar{p},p) + (g_E-\tilde{g}_T)\,A^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{-,D_s\phi}(\bar{p},p)\Big\} \\ &\quad + \frac{(e_C+e_Q/6)\,\tilde{g}_H}{4\,f^2\,M_V^2}\,\Big\{(\tilde{g}_V+g_T)\,C^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{+,DD^*K^*}(\bar{p},p) + 2\,\tilde{g}_V\,\bar{C}^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{DD^*K^*}(\bar{p},p) \\ &\qquad\qquad + (\tilde{g}_V-g_T)\,C^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{-,DD^*K^*}(\bar{p},p)\Big\} \\ &\quad + \frac{(e_C-e_Q/3)\,\tilde{g}_H}{8\,f^2\,M_V^2}\,\Big\{(\tilde{g}_V+g_T)\,C^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{+,D_sD_s^*\phi}(\bar{p},p) + 2\,\tilde{g}_V\,\bar{C}^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{D_sD_s^*\phi}(\bar{p},p) \\ &\qquad\qquad + (\tilde{g}_V-g_T)\,C^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{-,D_sD_s^*\phi}(\bar{p},p)\Big\} \\ &\quad + \frac{e_A\,g_P\,\tilde{g}_H}{12\,f^3\,m_V}\,D^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{DKK^*}(\bar{p},p) + \frac{e_A\,g_P\,\tilde{g}_H}{9\,f^3\,m_V}\,D^{\bar{\alpha}\bar{\beta},\mu,\alpha\beta}_{D_s\eta\phi}(\bar{p},p)\,. \end{aligned} \tag{124}$$

6 Numerical results

We confront the results of the previous sections with the experimental data on the radiative and strong decays of the scalar and axial-vector D_s-mesons reviewed in the introduction.

Our prediction of 140 keV for the isospin-violating strong width $D^*_{s0}(2317)^\pm \to D_s(1968)^\pm\,\pi^0$ is compatible with the empirical bound $\Gamma < 3.8$ MeV [23] but this comparison does not provide any significant constraint on the underlying coupled-channel dynamics. The present upper limit on the ratio of the radiative to pionic decay width [21]

$$\frac{\Gamma\,[D^*_{s0}(2317)^\pm \to D^*_s(2112)^\pm\,\gamma]}{\Gamma\,[D^*_{s0}(2317)^\pm \to D_s(1968)^\pm\,\pi^0]} < 0.059 \tag{125}$$

implies for the decay constant $d_{0^+\to\gamma\,1^-}$ defined in (86) the inequality,

$$\Big|d_{0^+\to\gamma\,1^-}\Big| < 0.117\,\mathrm{GeV}^{-1}\,, \tag{126}$$

using our predicted value for the $D^*_{s0} \to D_s\,\pi^0$ decay width (140 keV).

The total width of the $\mathrm{D}^*_{s1}(2460)^\pm$ meson is less than 3.5 MeV [23]. Our prediction of 140 keV for the isospin-violating strong decay width $D^*_{s1}(2460) \to D^*_s(2112)\,\pi^0$ is compatible with that upper bound but this is again not very significant. The constraints on the radiative decays of the $\mathrm{D}^*_{s1}(2460)^\pm$ to the $\mathrm{D}_s(1968)^\pm$, the $\mathrm{D}^*_s(2112)^\pm$ and the $\mathrm{D}^*_{s0}(2317)^\pm$ given in (3), (4) and (5) imply the following relations for the decay constants $d_{1^+\to\gamma\,0^-}$, $d_{1^+\to\gamma\,0^+}$ and $d^{(1,2)}_{1^+\to\gamma\,1^-}$ introduced in (97), (107) and (114),

$$\Big|d_{1^+\to\gamma\,0^-}\Big| = 0.138\,^{+0.012}_{-0.014}\,\mathrm{GeV}^{-1}\,, \qquad \Big|d_{1^+\to\gamma\,0^+}\Big| < 0.665\,\mathrm{GeV}^{-1}\,,$$
$$\Big|d^{(1)}_{1^+\to\gamma\,1^-}\Big|^2 + (1.164)^2\,\Big|d^{(2)}_{1^+\to\gamma\,1^-}\Big|^2 < \Big(0.39\Big)^2\,. \tag{127}$$

It is interesting to confront the empirical constraints (126, 127) to the predictions of heavy-quark symmetry. To leading order, the heavy-quark symmetry implies the relations

$$M_c\,d_{0^+\to\gamma\,1^-} = M_c\,d_{1^+\to\gamma\,0^-} = d^{(1)}_{1^+\to\gamma\,1^-} = d^{(2)}_{1^+\to\gamma\,1^-} \equiv d\,, \tag{128}$$

where $M_c \simeq M_V$ is a typical mass of a charmed meson. The result (128) can be derived from [10] by a matching of corresponding decay amplitudes. In the heavy-quark mass limit the parameter d scales linearly with the charm quark mass. The value given in (127) for $\Big|d_{1^+\to\gamma\,0^-}\Big|$ suggests the range $0.25 < |d| < 0.30$ for $M_c = M_V = 2000$ MeV. This value is barely compatible with the bound (126) and requires that $\Big|d_{0^+\to\gamma\,1^-}\Big|$ be close to that upper bound.

We discuss the electromagnetic decay parameters obtained using the expressions derived in Sections 4 and 5. The contributions from the KD and ηD_s

channels are shown in Table 3 for radiative transitions between scalar and vector states and in Table 4 for the radiative decay of the 1^+ to the 1^- state. The first column displays contributions involving the 4-point vertices (54) and (60). The second column shows the effect of anomalous processes and the third column contributions induced by the light vector mesons as intermediate states.

We consider the first column of these tables and try to reproduce the con-

Table 4
Contributions to the decay parameters $d^{(1)}_{1^+\to\gamma\,1^-}$ and $d^{(2)}_{1^+\to\gamma\,1^-}$ implied by (122). We use the same coupling constants as in Table 3

straints (126) and (127) using these terms only and the empirical value $g_P \simeq 0.57$. This exercise leads immediately to the conclusion that g_P and e_P must have opposite signs. Adding constructively the contributions from the KD and $\eta\, D_s$ channels would produce decay parameters that are much too large. We recall that e_P parameterizes gauge-invariant 4-point vertices describing the process where a D-meson emits a photon and a charged Goldstone boson simultaneously. Such interactions must be taken into account in effective field theories. The parameter e_P can be varied to achieve consistency with (126) and (127). To fit the $1^+ \to \gamma\, 0^-$ decay, the range of values for e_P is limited to the intervals $-0.57 < e_P < -0.49$ and $-1.50 < e_P < -1.42$. The constraints on the process $1^+ \to \gamma\, 1^-$ suggest $-1.54 < \tilde{e}_P < -0.84$ for $g_P = \tilde{g}_P = 0.57$. From the 0^+ decay we deduce $-2.08 < e_P < -1.37$. With $e_P = \tilde{e}_P \simeq -1.50$ we arrive at an acceptable scenario, given the assumption of Section 3 that the chiral power assigned to the e_P vertex is promoted from order Q_χ^3 to order Q_χ^2. The corresponding decay parameters are collected in the first column of Table 5. We observe that this scenario, though compatible with the constraints (126) and (127), is characterized by decay parameters in significant disagreement with the heavy-quark symmetry relation (128).

A value of e_P of the order of -1.5 has many consequences. As mentioned in the discussion following (61), this coupling is unnaturally large and points to the effectiveness of the theory. It also induces very important cancellations in the KD channel and between the KD and the ηD_s channels. The $D^*_{s0}(2317) \to \gamma\, D^*_s(2112)$ transition is actually dominated by the contribution of the ηD_s channel. The corresponding radiative width is 2.85 keV and the calculated value for the ratio (2) is 0.02. The comparison with other coupled-channel calculations is not easy as the mechanism driving the $D^*_{s0}(2317) \to \gamma\, D^*_s(2112)$ transition is not simple. Our radiative width is larger than the value of 0.49 keV obtained in [18] but we note that similar destructive effects between channels are observed in both approaches. Our result is quantitatively comparable to the radiative width of ∼1 keV found in [19] in a molecular picture, despite the fact that the ηD_s channel is not taken into account in [19] and important in our work as well as in [18]. This particular example illustrates the need for a consistent description of the spectroscopic properties of the D_s-mesons guided by general principles such as strong interaction symmetries. For the decays $D^*_{s1}(2460) \to \gamma\, D_s(1968)$, $D^*_{s1}(2460) \to \gamma\, D_{s0}(2317)$ and $D^*_{s1}(2460) \to \gamma\, D^*_s(2112)$, we obtain partial widths of 50 keV, 0 and 18 keV respectively (assuming always a strong width of 140 MeV). We stress that performing a formal expansion of the full expressions for the decay parameter in the inverse charm-quark mass leads to results that are compatible with the expectation from the heavy-quark symmetry. With phenomenological charm quark masses, the decay parameters obtained for the KD channel distort the pattern implied by the relation (128) obtained in the limit of infinitely heavy charm quarks. Such breaking pattern is even larger in the ηD_s channel. We note also from the numbers provided in Tables 3 and 4 that the contribution proportional to

	I)	II)	III)	IV)
$d_{0^+\to\gamma\,1^-}\,[\mathrm{GeV}^{-1}]$	+0.069	+0.035	−0.003	+0.073

$d_{1^+\to\gamma\,0^+}\,[\mathrm{GeV}^{-1}]$	0	+0.055	+0.055	+0.055
$d^{(1)}_{1^+\to\gamma\,1^-}$	−0.129	−0.097	−0.105	−0.090
$d^{(2)}_{1^+\to\gamma\,1^-}$	−0.282	−0.251	−0.251	−0.251

Table 5
Decay constants that are implied by $e_P = \tilde{e}_P = -1.50$ and $g_H = \tilde{g}_H = \hat{g}_H = 0$. The values used for e_A, $e_C = \tilde{e}_C$ and $e_Q = \tilde{e}_Q$ are discussed in the text. The four scenarios are characterized by I) $e_A = 0$ and $e_Q = e_C = 0$, II) $e_A = 0$, III) $e_A > 0$ and IV) $e_A < 0$. We use $f = 90$ MeV, $m_V = 776$ MeV, $M_V = 2000$ MeV.

g_P is larger in the ηD_s channel than in the KD channel. This is because there is only one contribution in the ηD_s channel while there are two contributions of opposite sign in the KD channel corresponding to the graphs where the photon couples to the K^+ or to the D^+.

We display the effect of the anomalous contributions in the second column of Tables 3 and 4. Without light vector mesons as explicit degrees of freedom, these terms determine entirely the $1^+ \to \gamma\, 0^+$ process. According to Appendix A, we should take $e_C \simeq 0.13$ and adjust the value of e_Q to the channel under consideration ($e_Q \simeq 0.91$ for the KD channel and $e_Q \simeq 0.52$ for the ηD_s channel). Given the coupling constants of Table 2, we predict $d_{1^+\to\gamma\,0^+} = 0.055$ GeV^{-1}, a result compatible with the bound of (127).

We discuss now the effects induced by the presence of light vector mesons when they do not couple directly to the scalar and axial-vector molecules ($g_H = \tilde{g}_H = \hat{g}_H = 0$) but influence their radiative decays as intermediate states through the anomalous vertex introduced in (62). This contribution is proportional to e_A and given in the third column of Tables 3 and 4. The parameter e_A exhibits significant flavour SU(3) breaking as indicated in (64). To take it into account we use

$$\begin{aligned} &e_A^{(\eta\, D_s)} = e_A^{(\phi\to\gamma\,\eta)} \simeq \pm 0.053\,,\\ &e_A^{(K\, D)} = 2\, e_A^{(K^{*0}\to\gamma\, K^0)} - e_A^{(K^{*+}\to\gamma\, K^+)} \simeq \pm 0.148\,, \end{aligned} \tag{129}$$

in the ηD_s and KD channels respectively. The phase of the parameter e_A is not determined by experiment. We consider both signs and provide the numerical values of the electromagnetic decay parameters in the third and fourth columns of Table 5 for e_A >0 and e_A <0. The phases and the size of the parameters g_T, g_E, $\tilde{g}_T$ and $\tilde{g}_V$ were estimated in Section 3 from the assumption of universally coupled light vector mesons, together with the ansatz of a combined heavy-quark and flavour SU(4) symmetry. We used the values $\tilde{g}_V \simeq 0.71$,

$g_E = g_P$ and $g_T = \tilde{g}_T = 0.5\, m_V\, g_P/M_V$ with $g_P = 0.57$. We caution that these numbers were derived with significant approximations. As can be seen in Table 5, the sign of e_A matters mostly for the radiative decay width of the $D^*_{s0}(2317)$: this width is extremely small for $e_A > 0$ (5.4 eV) and much larger for $e_A < 0$ (3.2 keV). An accurate measurement of the $D^*_{s1}(2460) \to \gamma\, D^*_s(2112)$ decay width would therefore be most helpful in determining whether the Lagrangian (62) leads to constructive or destructive interference effects in that quantity. We note that the $K^+\, D^0$ and $K^0\, D^+$ channels contribute to the decay amplitudes with opposite signs, the contribution of the $K^0\, D^+$ channel being twice as large as the contribution of the $K^+\, D^0$ channel.

We enlarge the discussion of the role played by light vector mesons by assuming that the K^*D^* and $\phi\, D^*_s$ channels can couple directly to the scalar and axial-vector molecules and the K^*D and $\phi\, D_s$ channels to the axial-vector molecules through the interactions defined in (80). In the heavy-quark mass limit, the coupling constants are equal, i.e. $\tilde{g}_H = g_H = \hat{g}_H \neq 0$.

We consider first the transition $1^+ \to \gamma\, 0^+$ between molecules. The corresponding decay parameter reads

$$\begin{aligned} 10\, \times\, d_{1^+\to\gamma\, 0^+}[\mathrm{GeV}^{-1}] &= \hat{g}_H\, g_H \Big[1.187 - 0.377\Big] \\ &- \tilde{g}_H\, g_H \Big[5.363\,(e_C + e_Q/6)\, + 5.607\,(e_C - e_Q/3)\,\Big] \\ &+ e_A^{(KD)} \Big[0.429\, g_H + 9.244\, \tilde{g}_H\Big] + e_A^{(\eta D_s)} \Big[1.704\, g_H + 13.62\, \tilde{g}_H\Big]\,, \end{aligned} \tag{130}$$

where we separate the contributions from channels involving the D and D_s mesons. In the first term, the numbers 1.187 and -0.377 represent the contributions from the $\phi\, D^*_s$ and the K^*D^* channels respectively. Similarly the contributions proportional to $e_C + e_Q/6$ and $e_C - e_Q/3$ reflect the $K^*D \to K^*D^*$ and $\phi\, D_s \to \phi\, D^*_s$ transitions. With the values of e_A, e_Q and e_C discussed above, we may use (130) and (127) to constrain the parameters $g_H, \tilde{g}_H$ and $\hat{g}_H$. In the heavy-quark limit ($g_H = \tilde{g}_H = \hat{g}_H$), we derive the conditions

$$-\,10.5 < g_H < 2.18\,, \qquad\qquad -2.18 < g_H < 10.5\,, \tag{131}$$

for the positive and negative values of e_A respectively. Clearly the result (131) does not provide a strong constraint on the size of the parameter g_H.

We turn to the radiative transitions of the scalar and axial-vector molecules to 0^- and 1^- ground states. We display in Tables 6 and 7 the contributions of the channels involving light vector mesons to these decays. The terms shown in Table 6 correspond to the expressions (165) and (105) (obtained in Appendix D and in Section 5) for the $0^+ \to \gamma 1^-$ transition and (169) derived in Appendix D for the $1^+ \to \gamma 0^-$ transition. The terms quoted in Table 7 correspond to

	$10\,\times\, d_{0^+\to\gamma\,1^-}\,[\mathrm{GeV}^{-1}]$	
$K^* D^*$	$+10.66\, g_T + 2.976\,\tilde g_V$	$+1.758\, e_T + 2.343\,\tilde e_E - 2.765\,\tilde e_V$

Table 6
Contributions to the decay parameters $d_{0^+\to\gamma\,1^-}$ and $d_{1^+\to\gamma\,0^-}$ implied by the light vector meson couplings as given by (165, 105, 169). The various terms have to be multiplied by either $g_H, \tilde g_H$ or $\hat g_H$ as indicated in the first column.

the expressions (124) and (179) (obtained in Section 5 and in Appendix G) for the $1^+\to\gamma 1^-$ transition. They involve the additional parameters $e_T, \tilde e_T, e_V, \tilde e_V$ and $e_E, \tilde e_E$ introduced in (66). Clearly, it is not possible to determine these numbers by the constraints (126) and (127) only.

To achieve a qualitative understanding of these terms, we assume that all parameters are correlated as dictated by the heavy-quark mass limit (i.e. $e_P = \tilde e_P, e_V = \tilde e_V$,...). In this limit, there remain five unknown parameters g_H, e_P, e_V, e_T and e_E. One may expect to learn little from the constraints (126) and (127) only. However, this is not quite so. For specific values of g_H and e_P, one can always adjust the values for e_V, e_T and e_E so as to reproduce a given value of the decay parameter $d_{0^+\to\gamma 1^-}$ and the partial decay widths of the process $1^+\to\gamma\,0^-$ and $1^+\to\gamma\,1^-$ derived in (126) and (127). We assume as before $\tilde g_V \simeq 0.71$, $g_E = g_P$ and $g_T = \tilde g_T = 0.5\, m_V\, g_P/M_V$ with $g_P = 0.57$. The requirement that the parameters e_V, e_T and e_E be real, as implied by

		$-(\tilde{e}_C+\tilde{e}_Q/3)\,(0.443\,g_T-0.014\,\tilde{g}_V)$

Table 7
Contributions to the decay parameters $d^{(1)}_{1^+\to\gamma\,1^-}$ and $d^{(2)}_{1^+\to\gamma\,1^-}$ implied by the light vector meson couplings as given by (124, 179). The various terms have to be multiplied by either $\tilde{g}_H$ or $\hat{g}_H$ as indicated in the first column.

charge conjugation symmetry, defines stringent conditions on the ranges of values allowed for g_H and e_P. Note that the latter are determined by quadratic equations, the solution of which involves a square root. The constants e_V, e_T and e_E be real numbers only if the argument of that square root is positive. For a given value of e_P, we derive the condition that the parameter g_H has to be confined in a small interval

$$g_H^{crit,-} < g_H < g_H^{crit,+}\,. \tag{132}$$

	I)	II)
$d_{0^+ \to \gamma\, 1^-}\,[\mathrm{GeV}^{-1}]$	$+0.057$	$+0.104$
$d_{1^+ \to \gamma\, 0^-}\,[\mathrm{GeV}^{-1}]$	-0.139	-0.140
$d_{1^+ \to \gamma\, 0^+}\,[\mathrm{GeV}^{-1}]$	-0.043	$+0.091$
$d^{(1)}_{1^+ \to \gamma\, 1^-}$	$+0.303$	$+0.278$
$d^{(2)}_{1^+ \to \gamma\, 1^-}$	$+0.202$	$+0.071$

Table 8
Decay constants obtained using $e_P = e_V = e_T = e_E = 0$ and $\tilde{e}_P = \tilde{e}_V = \tilde{e}_T = \tilde{e}_E = 0$. In set I) we use $e_A > 0$ with $g_H = \tilde{g}_H = \hat{g}_H = -0.46$. Set II) assumes $e_A < 0$ and $g_H = \tilde{g}_H = \hat{g}_H = -0.25$. We assume $f = 90$ MeV, $m_V = 776$ MeV, $M_V = 2000$ MeV.

We discriminate between the scenarios implied by positive or negative values of the parameter e_A, for which we find respectively

$$g_H^{crit,\pm} \simeq -0.390 + 1.332\, d_{0^+ \to \gamma\, 1^-}[\mathrm{GeV}^{-1}] - 0.242\, e_P \pm 0.131\,,$$
$$g_H^{crit,\pm} \simeq -0.285 + 0.751\, d_{0^+ \to \gamma\, 1^-}[\mathrm{GeV}^{-1}] - 0.137\, e_P \pm 0.074\,. \tag{133}$$

We checked the stability of this result against reasonable variations of the parameters g_V, g_T and g_E. In (133) we allow the decay parameter $d_{0^+ \to \gamma\, 1^-}$ to take any value. The result (133) is very significant: for any reasonable range of e_P it requires the coupling constant g_H to be quite small, typically $|g_H| < 0.5$. This justifies in retrospect the coupled-channel computation of Section 2, which assumed that the light vector mesons are not relevant for the formation of the scalar and axial-vector D_s molecules.

The light vector mesons may nevertheless change the radiative decay parameters significantly because of cancellations between terms. Our main result is that the introduction of light vector mesons leads to a very consistent picture. We obtain values for all decay parameters that are compatible with the empirical constraints using vanishing values for all gauge-invariant counter terms $e_P = e_V = e_T = e_E = 0$ and $\tilde{e}_P = \tilde{e}_V = \tilde{e}_T = \tilde{e}_E = 0$. In such a scenario there is one free parameter only, $g_H = \tilde{g}_H = \hat{g}_H$, which can be dialed to recover all empirical constraints. The results for the positive and negative e_A scenarios are collected in Table 8. It is interesting to observe that we predict a negative decay constant for the $1^+ \to \gamma\, 0^-$ decay contradicting the naive expectation of heavy-quark symmetry. We emphasize that this follows even though performing a formal expansion of the full expressions for the decay parameter in the inverse charm-quark mass leads to results compatible with the expectation from the heavy-quark symmetry. Such an expansion assumes for instance $m_\phi \ll M_c$, which is not realized too well in nature. Our results provide a physical justification for promoting the counter terms proportional to e_P and $\tilde{e}_P$ to chiral order Q_χ^2 rather than the expected power Q_χ^3. Once the light vector mesons are introduced as important physical degrees of freedom, the naturalness assumption for the residual size of e_P and $\tilde{e}_P$ appears justified.

We emphasize that it does not appear possible to predict precise values for the decay parameters. The results of Table 8 should be viewed as possible and natural scenarios. We provide therefore the radiative widths associated with the decay constants of Table 8, assuming the strong width of the $\mathrm{D}^*_{s0}(2317)^\pm$ and $\mathrm{D}^*_{s1}(2460)^\pm$ to be 140 keV, as a mere indication of their expected range. For the scenarios labeled I and II, we find $\Gamma_{0^+\to\gamma\,1^-} = 1.94$ and 6.47 keV, $\Gamma_{1^+\to\gamma\,0^-}$=44.50 and 45.14 keV, $\Gamma_{1^+\to\gamma\,0^+}$=0.13 and 0.59 keV and $\Gamma_{1^+\to\gamma\,1^-}$=21.8 and 12.47 keV respectively. Precise unquenched lattice QCD simulations for the hadronic coupling constants of the Goldstone bosons and light vector mesons to the D-mesons would be very helpful.

7 Summary

Based on the chiral Lagrangian properties of scalar and axial-vector meson molecules with open-charm content were studied. Chiral correction terms were incorporated systematically in the coupled-channel dynamics, where we relied on constraints from large-N_c QCD and the heavy-quark symmetry. We focused on the $D^*_{s0}(2317)$ and $D^*_{s1}(2460)$ states and computed their isospin-violating hadronic and electromagnetic decay widths. In order to establish manifestly gauge-invariant results for the electromagnetic decay parameters the spin-one particles were represented in terms of antisymmetric tensor fields rather than by the more conventional vector fields. The role of explicit light vector mesons in the radiative decays was investigated.

The main findings of this work for the strong and radiative decay widths of the $D^*_{s0}(2317)$ and $D^*_{s1}(2460)$ states can be summarized as follows.

The hadronic isospin-violating decay widths of both the $D^*_{s0}(2317)$ and $D^*_{s1}(2460)$ states are predicted to be 140 keV. Chiral corrections to order Q_χ^2 lead to a significant enhancement of these widths. We point out the importance of treating consistently the $\eta\,\pi$ mixing and the isospin-mixing effects in the KD system. The observed upper limits on these strong widths of 3.8 and 3.5 MeV respectively do not provide any useful constraint on the theory yet.

The radiative decay parameters of the $D^*_{s0}(2317) \to \gamma\, D^*_s$ and $D^*_{s1}(2460) \to \gamma\, D_s, \gamma\, D^*_s$ and $D^*_{s1}(2460) \to \gamma\, D^*_{s0}(2317)$ were computed in the hadrogenesis conjecture. They involve only one-loop diagrams. We find that both the ηD_s and $\eta\, D^*_s$ channels contribute significantly and that large cancellations occur between the different channels. The results are compatible with all empirical constraints if one gauge-invariant contact term is considered to be more important than expected from a naive naturalness assumption. The decay parameters are subject to a cancellation mechanism, which makes a prediction of their precise values unreliable at the moment.

When considering light vector mesons as explicit degrees of freedom coupled to the scalar and axial-vector molecules, radiative decay parameters that are compatible with the empirical constraints, can be obtained without envoking subleading contact terms. We understand this effect as an indication of the dynamical role of light vector mesons in the electromagnetic transition processes. We predict that the $D^*_{s0}(2317)$ and $D^*_{s1}(2460)$ have small coupling strength to the $K^* D^*$ and $\phi\, D^*_s$ channels despite the decisive role played by these degrees of freedom in the radiative decay processes.

Finally we point out that the invariant $\eta\, D^*$ invariant mass distribution shows a signal of a member of an exotic axial-vector sextet at a mass of 2568 MeV and with a width of 18 MeV. While that state decouples from the πD^* spectrum, its heavy-quark partner defines a narrow dip at a mass of 2410 MeV and with a width of 2 MeV in the $\pi\, D$ mass distribution.

Appendix A

The modulus of the coupling constant g_P appearing in the Lagrangian (37) can be determined from the measured strong D*-meson decay widths [21]

$$\begin{aligned}
&\Gamma_{D^{*+}\to D^0\,\pi^+} = (65.0 \pm 14.9)\,\mathrm{keV}\,,\\
&\Gamma_{D^{*+}\to D^+\,\pi^0} = (29.5 \pm 6.8)\,\mathrm{keV}\,.
\end{aligned} \tag{134}$$

Using

$$\begin{aligned}
&\Gamma_{D^{*+}\to D^0\,\pi^+} = \frac{|g_P|^2}{12\,\pi}\,\frac{q^3_{cm}}{f^2}\,, \qquad && q_{cm} = 39.60\,\mathrm{MeV}\,,\\
&\Gamma_{D^{*+}\to D^+\,\pi^0} = \frac{|g_P|^2}{24\,\pi}\,\frac{q^3_{cm}}{f^2}\,, \qquad && q_{cm} = 38.30\,\mathrm{MeV}\,,
\end{aligned} \tag{135}$$

leads to

$$|g_P| = 0.57 \pm 0.07\,. \tag{136}$$

The modulus of the coupling constants e_Q and e_C introduced in the Lagrangian (55) can be determined from the observed branching ratios for the radiative decays $D^{*+} \to D^+\,\gamma$, $D^{*0} \to D^0\,\gamma$ and $D_s^{*+} \to D_s^+\,\gamma$ [21]. The total widths of the D^{*0} and of the D_s^{*+} are not known. They are the sums of the strong and radiative widths. The strong widths associated with π^0 emission,

$$\begin{aligned}
\Gamma_{D^{*0}\to D^0\,\pi^0} &= \frac{|g_P|^2}{24\,\pi}\,\frac{q_{cm}^3}{f^2} \simeq 42\,\text{keV}\,, \qquad\qquad q_{cm} = 43.12\,\text{MeV}\,,\\
\Gamma_{D_s^{*+}\to D_s^+\,\pi^0} &= \frac{|\epsilon\,g_P|^2}{18\,\pi}\,\frac{q_{cm}^3}{f^2} \simeq \epsilon^2\,77\,\text{keV}\,, \qquad q_{cm} = 47.87\,\text{MeV}\,,
\end{aligned} \tag{137}$$

are calculated using the value of $|g_P|$ derived above. ϵ is the $\pi_0\eta$ mixing angle (10). From the data on the $D^{*+} \to D^+\gamma$ partial width and the known branching ratios of the D^{*0} and D_s^{*+} into the $\pi^0 D^0$ and $\pi^0 D_s^+$ channels [21], we obtain

$$\begin{aligned}
\Gamma_{D^{*+}\to D^+\,\gamma} &= \;(1.5 \pm 0.8)\,\text{keV}\,,\\
\Gamma_{D^{*0}\to D^0\,\gamma} &= (\Gamma_{D^{*0}\to D^0\,\gamma} + 42\,\text{keV}) \times (0.381 \pm 0.029)\\
&= \;(26.0 \pm 3)\,\text{keV}\,,\\
\Gamma_{D_s^{*+}\to D_s^+\,\gamma} &= (\Gamma_{D_s^{*+}\to D_s^+\,\gamma} + \epsilon^2\,77\,\text{keV}) \times (0.942 \pm 0.007)\\
&= \epsilon^2\,(1328 \pm 180)\,\text{keV}\,.
\end{aligned} \tag{138}$$

From the Lagrangian (55), we derive

$$\begin{aligned}
\Gamma_{D^{*+}\to D^+\,\gamma} &= \frac{M_{D^{*+}}^2}{4\,\pi}\,\frac{(e_Q - 3\,e_C)^2}{9\,M_V^4}\,q_{cm}^3\,, \qquad q_{cm} = 135.78\,\text{MeV}\,,\\
\Gamma_{D^{*0}\to D^0\,\gamma} &= \frac{M_{D^{*0}}^2 4\,\pi}{}\,\frac{(2\,e_Q + 3\,e_C)^2}{9\,M_V^4}\,q_{cm}^3\,, \qquad q_{cm} = 137.16\,\text{MeV}\,,\\
\Gamma_{D_s^{*+}\to D_s^+\,\gamma} &= \frac{M_{D_s^{*+}}^2}{4\,\pi}\,\frac{(e_Q - 3\,e_C)^2}{9\,M_V^4}\,q_{cm}^3\,, \qquad q_{cm} = 138.91\,\text{MeV}\,.
\end{aligned} \tag{139}$$

From the first two constraints of (138), we get

$$|e_Q - 3\,e_C| \simeq 0.537^{+0.128}_{-0.170}\,, \qquad |2\,e_Q + 3\,e_C| \simeq 2.201^{+0.124}_{-0.131}\,,$$

$$\textit{i.e.} \qquad e_Q = 0.91 \pm 0.10\,, \qquad e_C = 0.13 \pm 0.05\,, \tag{140}$$

where we assume $M_V = 2000$ MeV. Using (140) and taking $\epsilon \simeq 0.01$ in the third constraint overestimates the $D_s^{*+} \to D_s^+\gamma$ decay rate by an order of magnitude ($\sim$1.9 keV rather than ~ 0.13 keV). This may be a signal of SU(3) breaking effects in e_Q or suggest the need for an increased value of ϵ. For $\epsilon = 0.01$ and $e_C = 0.13$, an effective $e_Q \simeq 0.52$ reproduces the empirical width.

The modulus of the coupling constant e_A appearing in (62) is determined from the radiative decay of the light vector mesons, $K^{*0} \to K^0\gamma, K^{*\pm} \to K^\pm\gamma$ and $\phi \to \eta\gamma$. From the Lagrangian (62), we obtain

$$
\begin{aligned}
\Gamma_{K^{*\pm}\to K^\pm\gamma} &= \frac{|e_A|^2}{24\times 144\,\pi}\,\frac{m^5_{K^{*\pm}}}{m_V^2\,f^2}\left(1-\frac{m^2_{K^\pm}}{m^2_{K^{*\pm}}}\right)^3 ,\\
\Gamma_{K^{*0}\to K^0\gamma} &= \frac{|e_A|^2}{24\times \;\;36\,\pi}\,\frac{m^5_{K^{*0}}}{m_V^2\,f^2}\left(1-\frac{m^2_{K^0}}{m^2_{K^{*0}}}\right)^3 ,\\
\Gamma_{\,\phi\to\eta\,\gamma} &= \frac{|e_A|^2}{24\times \;\;54\,\pi}\,\frac{m^5_{\phi}}{m_V^2\,f^2}\left(1-\frac{m^2_{\eta}}{m^2_{\phi}}\right)^3 ,
\end{aligned}
\tag{141}
$$

where we will assume $f = 90$ MeV and $m_V = 776$ MeV. The experimental decay widths [21] imply conflicting values for e_A. We find

$$
\begin{aligned}
\Gamma_{K^{*0}\to K^0\gamma} &= (116\,\pm\,10)\,\text{keV}\,, &&\to && |e_A| = 0.119\pm 0.006\,,\\
\Gamma_{K^{*\pm}\to K^\pm\gamma} &= (50\,\pm\,5)\,\text{keV}\,, &&\to && |e_A| = 0.090\pm 0.004\,,\\
\Gamma_{\phi\to\eta\,\gamma} &= (55.38\,\pm\,1.68)\,\text{keV}\,, &&\to && |e_A| = 0.053\pm 0.001\,.
\end{aligned}
\tag{142}
$$

Appendix B

To work out the implications of the heavy-quark symmetry of QCD, it is useful to introduce auxiliary fields, $P_\pm(x)$ and $P^\mu_\pm(x)$ such that

$$
\begin{aligned}
D(x) \;\; &= e^{-i\,(v\cdot x)\,M_c}\,P_+(x) + e^{+i\,(v\cdot x)\,M_c}\,P_-(x)\,,\\
D^{\mu\nu}(x) &= i\,e^{-i\,(v\cdot x)\,M_c}\left\{v^\mu\,P^\nu_+(x) - v^\nu\,P^\mu_+(x) + \frac{i}{M_c}\left(\partial^\mu P^\nu_+ - \partial^\nu P^\mu_+\right)\right\}\\
&\quad + i\,e^{+i\,(v\cdot x)\,M_c}\left\{v^\mu\,P^\nu_-(x) - v^\nu\,P^\mu_-(x) - \frac{i}{M_c}\left(\partial^\mu P^\nu_- - \partial^\nu P^\mu_-\right)\right\},
\end{aligned}
\tag{143}
$$

with a 4-velocity normalized by $v^2 = 1$. The mass M_c is an averaged value of the pseudoscalar and vector charmed meson ground state masses. The fields $P_\pm(x)$ and $P^\mu_\pm(x)$ are therefore varying slowly in space and time and their derivatives are small compared to $M_c\, v_\alpha\, P$. In the limit $M_c \to \infty$, these derivatives can be neglected.

We rewrite the interaction terms introduced in (37, 60, 65) in terms of the auxiliary fields. Restricting the Lagrangian density to the 'plus' components and dropping that index for simplicity, we have

$$\begin{aligned}
\mathcal{L} = {} & i\,\frac{g_P\, M_c}{f}\,\Big\{ P_\mu\,(\partial^\mu \Phi)\,\bar{P} - P\,(\partial^\mu \Phi)\,\bar{P}_\mu \Big\} + i\,\frac{\tilde{g}_P\, M_c}{f}\, v_\mu\, \epsilon^{\mu\nu\alpha\beta}\, P_\nu\,(\partial_\alpha \Phi)\,\bar{P}_\beta \\
& - \frac{g_V\, M_c}{f}\, v_\mu\, P\,(\partial_\alpha V^{\alpha\mu})\,\bar{P} + \frac{\tilde{g}_V\, M_c}{f}\, v_\mu\, P_\nu\,(\partial_\alpha V^{\alpha\mu})\,\bar{P}^\nu \\
& + i\,\frac{\tilde{g}_T\, M_c^2}{4\,f}\, v_\alpha\, \epsilon^{\mu\nu\alpha\beta}\,\Big\{ P_\beta\, V_{\mu\nu}\,\bar{P} - P\, V_{\mu\nu}\,\bar{P}_\beta \Big\} + i\,\frac{g_T\, M_c^2}{2\,f}\, P_\mu\, V^{\mu\nu}\,\bar{P}_\nu \\
& + \frac{e_P\, M_c}{f}\, F^{\mu\nu}\,\Big\{ P_\mu\,[(\partial_\nu \Phi),\, Q]\,\bar{P} - P\,[(\partial_\nu \Phi),\, Q]\,\bar{P}_\mu \Big\} \\
& + \frac{\tilde{e}_P\, M_c}{f}\, F_{\mu\nu}\, v_\tau\, \epsilon^{\tau\alpha\mu\beta}\, P_\alpha\,[(\partial_\nu \Phi),\, Q]\,\bar{P}_\beta \\
& + \cdots\,,
\end{aligned} \tag{144}$$

where the ellipses stand for additional terms involving derivatives of the soft fields $P = P_+$ and $P^\mu = P^\mu_+$ and the 'minus' components. In deriving (144) we used the equation of motion of the auxiliary field $P^\mu_\pm(x)$,

$$\mp i\, M_c\, v_\mu\, P^\mu_\pm + \partial_\mu\, P^\mu_\pm = 0\,, \tag{145}$$

obtained from the equation of motion of the field $D^{\mu\nu}$,

$$\partial^\mu \partial_\alpha D^{\alpha\nu} - \partial^\nu \partial_\alpha D^{\alpha\mu} + M_c^2\, D^{\mu\nu} = 0\,. \tag{146}$$

The QCD action depends linearly on the charm-quark mass. The effective Lagrangian (144) should therefore be proportional to M_c. The coupling constants $g_{P,V}$ and $\tilde{g}_{P,V}$ must then approach a finite value in the limit of infinite charm-quark mass. The same argument requires the coupling constants g_T and $\tilde{g}_T$ to scale with $1/M_c$. The fact that there is no term proportional to g_E displayed in (144) signals that the corresponding interaction term is at least subleading in the heavy-quark mass expansion. Note that this observation is compatible with a possible finite and non-zero value of the asymptotic value of g_E in the heavy-quark mass limit.

In the limit of infinite quark mass, the fields $P_\pm$ and $P^\mu_\pm$ may be combined into a multiplet involving the 1^- and 0^- fields. Therefore the properties of pseudoscalar and vector states should be closely related. We follow the formalism developed in [26,27,28,29,30] and introduce the multiplet field H,

$$
\begin{aligned}
&H = \frac{1}{2}\left(1+\not{v}\right)\left(\gamma_\mu\, P_+^\mu + i\,\gamma_5\, P_+\right)\\
&\bar{H} = \gamma_0\, H^\dagger\, \gamma_0 = \left(P^\dagger_{+,\mu}\,\gamma^\mu + P^\dagger_+\, i\,\gamma_5\right)\frac{1}{2}\left(1+\not{v}\right),\\
&P_+^\mu\, v_\mu = 0\,, \qquad v^2 = 1\,,
\end{aligned}
\tag{147}
$$

in terms of which the interaction Lagrangian can be recast. Let S denote a transformation of the heavy-quark spin symmetry group $\mathrm{SU}(2)_v$ whose elements are characterized by the 4-vector θ^α with $\theta \cdot v = 0$. According to [56] under such a transformation the field H transforms as

$$
\begin{aligned}
&H \to e^{-i\,S_\alpha\,\theta^\alpha}\, H\,, \qquad && \bar{H} \to \gamma_0\,(e^{-i\,S_\alpha\,\theta^\alpha}\, H)^\dagger\,\gamma_0 = \bar{H}\, e^{+i\,S_\alpha\,\theta^\alpha}\,,\\
&S^\alpha = \frac{1}{2}\,\gamma_5\,[\not{v},\gamma^\alpha]\,, \qquad && S^\dagger_\alpha\,\gamma_0 = \gamma_0\, S_\alpha\,, \qquad [\not{v}, S_\alpha]_- = 0\,.
\end{aligned}
\tag{148}
$$

Under a Lorentz transformation characterized by the antisymmetric tensor $\omega_{\mu\nu}$, the spinor part of the fields transforms as

$$
\begin{aligned}
&H \to e^{i\,S_{\mu\nu}\,\omega^{\mu\nu}}\, H\, e^{-i\,S_{\mu\nu}\,\omega^{\mu\nu}}\,, \qquad && \bar{H} \to e^{i\,S_{\mu\nu}\,\omega^{\mu\nu}}\,\bar{H}\, e^{-i\,S_{\mu\nu}\,\omega^{\mu\nu}}\,,\\
&S_{\mu\nu} = \frac{i}{4}\,[\gamma_\mu, \gamma_\nu]\,.
\end{aligned}
\tag{149}
$$

Only the combinations where Dirac matrices are to the right of the field H or to the left of the field $\bar{H}$ are invariant under the spin group $SU_v(2)$. It is straightforward to construct those terms that can be matched to the structures given in (144). We introduce

$$
\begin{aligned}
\mathcal{L} = &-\frac{f_P}{2}\,\mathrm{tr}\left(H\,(\partial^\mu\Phi)\,\gamma_5\,\gamma_\mu\,\bar{H}\right) + i\,\frac{\bar{f}_P}{2}\,F^{\mu\nu}\,\mathrm{tr}\left(H\,\gamma_5\,\gamma_\mu\left[(\partial_\nu\,\Phi),\, Q\right]\bar{H}\right)\\
&-\frac{f_V}{2}\,\mathrm{tr}\,\left(H\,(\partial_\alpha V^{\alpha\mu})\,\gamma_\mu\,\bar{H}\right) + i\,\frac{\bar{f}_V}{2}\,F^{\mu\nu}\,\mathrm{tr}\,\left(H\,\gamma_\mu\left[(\partial^\alpha V_{\alpha\nu}),\, Q\right]\bar{H}\right)\\
&+\frac{f_T}{8}\,\mathrm{tr}\,\left(H\,V^{\mu\nu}\,\sigma_{\mu\nu}\,\bar{H}\right) - i\,\frac{\bar{f}_T}{8}\,\mathrm{tr}\;F^\mu{}_\nu\left(H\,[V^{\nu\alpha},\, Q]\,\sigma_{\mu\alpha}\,\bar{H}\right),\\
&+\frac{\bar{f}_E}{4}\,F^{\mu\nu}\,\mathrm{tr}\,\left(H\,\{V^{\mu\nu},\, Q\}\,\bar{H}\right),
\end{aligned}
\tag{150}
$$

where we note that the field H is a three-dimensional row in flavour space, each of its components consisting of a 4-dimensional Dirac matrix. We have

$$
\mathrm{tr}\,\gamma_5\,\gamma_\mu\,\gamma_\nu\,\gamma_\alpha\,\gamma_\beta = -4\,i\,\epsilon_{\mu\nu\alpha\beta}\,,
\tag{151}
$$

in our convention. Matching the expressions (144, 150) we obtain

$$
\begin{aligned}
&\frac{g_P\,M_c}{f} = \frac{\tilde g_P\,M_c}{f} = f_P\,, &&\frac{e_P\,M_c}{f\,m_V^2} = \frac{\tilde e_P\,M_c}{f\,m_V^2} = \bar f_P\,,\\
&\frac{g_V\,M_c}{f} = \frac{\tilde g_V\,M_c}{f} = f_V\,, &&\frac{e_V\,M_c}{f\,m_V^2} = \frac{\tilde e_V\,M_c}{f\,m_V^2} = \bar f_V\,,\\
&\frac{g_T\,M_c^2}{f} = \frac{\tilde g_T\,M_c^2}{f} = f_T\,, &&\frac{e_T\,M_c^2}{f} = \frac{\tilde e_T\,M_c^2}{f} = \bar f_T\,,\\
&\frac{e_E\,M_c^2}{f} = \frac{\tilde e_E\,M_c^2}{f} = \bar f_E\,. && \qquad (152)
\end{aligned}
$$

We turn to the terms (55, 57). Applying the ansatz (143) we derive

$$
\begin{aligned}
\mathcal{L}_{e.m.} = &\frac{i}{2}\,F^{\mu\nu}\,v^\alpha\,\epsilon_{\mu\nu\alpha\beta}\,\Big\{P^\beta\,\Big(e_C + e_Q\,Q\Big)\,\bar P - P\,\Big(e_C + e_Q\,Q\Big)\,\bar P^\beta\Big\}\\
&+ i\,F^{\mu\nu}\,P_\mu\,\Big(-\tilde e_C + \tilde e_Q\,Q\Big)\,\bar P_\nu + \cdots\,. \qquad (153)
\end{aligned}
$$

where we identify $M_c = M_V$ for convenience. Like in (144), we drop in (153) additional irrelevant terms. The interaction terms displayed in (153) are readily reproduced using the heavy-quark multiplet field H. We follow [48,50] and write

$$
\mathcal{L}_{e.m.} = +\frac{e_Q}{4}\,F_{\mu\nu}\,\mathrm{tr}\,H\,Q\,\sigma_{\mu\nu}\,\bar H + \frac{e_C}{4}\,F_{\mu\nu}\,\mathrm{tr}\,\sigma_{\mu\nu}\,H\,\bar H\,, \qquad (154)
$$

where the term proportional to e_Q respects the heavy-quark symmetry, but the term proportional to e_C breaks it. We expect $|e_Q| \gg |e_C|$ since the parameter e_C should vanish in the heavy-quark limit. The requirement that (153) and (154) agree yields the desired relations

$$
\tilde e_C = e_C\,, \qquad\qquad \tilde e_Q = e_Q\,. \qquad (155)
$$

Note that the empirical values (140) confirm the expectation $|e_Q| \gg |e_C|$.

Finally we provide an analysis of the effective resonance interaction terms (74, 80). Assuming a decomposition analogous to (143) for the resonance fields R and $R_{\mu\nu}$, we introduce a resonance multiplet field

$$
\begin{aligned}
&S = \frac{1}{2}\,\Big(1 + \not v\Big)\,\Big(\gamma_5\,\gamma_\mu\,R^\mu_+ + R_+\Big)\,,\\
&\bar S = \gamma_0\,S^\dagger\,\gamma_0 = \Big(R^\dagger_{+,\mu}\,\gamma_5\,\gamma_\mu + R^\dagger_+\Big)\,\frac{1}{2}\,\Big(1+\not v\Big)\,, \qquad v^\mu\,R^\mu_+ = 0\,, \qquad (156)
\end{aligned}
$$

where the field S transforms like the field H under a spin rotation (see 148). At leading order in a heavy-quark mass expansion, the interaction terms (74, 80) are described by

$$
\begin{aligned}
\mathcal{L} = \frac{f_H}{4}\,\mathrm{tr}\Big(S\,\gamma_\mu\,(\partial_\tau V^{\tau\mu})\,\bar{H} \;\; + H\,\gamma_\mu\,(\partial_\tau V^{\tau\mu})\,\bar{S}\Big) \\
+ \frac{f_R}{4}\,\mathrm{tr}\Big(S\,\gamma_5\,\gamma_\mu\,(\partial^\mu\Phi)\,\bar{H} + H\,\gamma_5\,\gamma_\mu\,(\partial^\mu\Phi)\,\bar{S}\Big)\,,
\end{aligned}
\tag{157}
$$

which implies the identifications

$$
\frac{g_R\,M_c}{f} = \frac{\tilde{g}_R\,M_c}{f} = f_R\,, \qquad \frac{g_H\,M_c^2}{f} = \frac{\tilde{g}_H\,M_c^2}{f} = \frac{\hat{g}_H\,M_c^2}{f} = f_H\,. \tag{158}
$$

Appendix C

All tensor integrals will be decomposed into scalar objects of the form

$$
\begin{aligned}
I_{ab} &= -i\int\frac{d^4l}{(2\pi)^4}\,S_a(l)\,S_b(l+p)\,, \qquad \bar{I}_{ab} = -i\int\frac{d^4l}{(2\pi)^4}\,S_a(l)\,S_b(l+\bar{p})\,, \\
J_{abc} &= +i\int\frac{d^4l}{(2\pi)^4}\,S_a(l)\,S_b(l+q)\,S_c(l+p)\,, \\
\bar{J}_{abc} &= +i\int\frac{d^4l}{(2\pi)^4}\,S_a(l)\,S_b(l+\bar{p})\,S_c(l+p)\,.
\end{aligned}
\tag{159}
$$

We introduce the two integrals J_{abc} and $\bar{J}_{abc}$ even though $J_{abc} = \bar{J}_{cba}$ as this redundancy will be used for a consistency check of the numerical simulation. The integrals I_{ab} and $\bar{I}_{ab}$ are ultraviolet divergent and read (see(15))

$$
\begin{aligned}
I_{ab}(s) &= \frac{1}{16\,\pi^2}\left(\frac{p_{ab}}{\sqrt{s}}\left(\ln\left(1-\frac{s-2\,p_{ab}\,\sqrt{s}}{m_b^2+m_a^2}\right)-\ln\left(1-\frac{s+2\,p_{ab}\sqrt{s}}{m_b^2+m_a^2}\right)\right)\right. \\
&\qquad\left. +\left(\frac{1}{2}\,\frac{m_b^2+m_a^2}{m_b^2-m_a^2}-\frac{m_b^2-m_a^2}{2\,s}\right)\ln\left(\frac{m_b^2}{m_a^2}\right)+1\right)+I_{ab}(0)\,, \\
p_{ab}^2 &= \frac{s-(m_a+m_b)^2}{4\,s}\Big(s-(m_a-m_b)^2\Big)\,,
\end{aligned}
\tag{160}
$$

where the logarithmic divergence sits in the subtraction term $I_{ab}(0)$. The difference $I_{ab}(s) - I_{ab}(0)$ is finite. According to the discussion of Section 3.3, we define the renormalized expressions

$$
I_{ab} \to I_{ab}(p^2) - I_{ab}(\mu_M^2)\,, \qquad \bar{I}_{ab} \to I_{ab}(\bar{p}^2) - I_{ab}(\mu_M^2)\,, \tag{161}
$$

with the matching scale μ_M. The integrals J_{abc} and $\bar{J}_{abc}$ are finite. They may be evaluated in terms of their dispersion-integral representations

$$J_{abc} = \int\limits_{(m_a+m_c)^2}^{\infty} \frac{d\,s}{\pi}\, \frac{\rho^{(+)}_{abc}(s)}{s-p^2-i\,\epsilon}\,, \qquad \bar{J}_{abc} = \int\limits_{(m_a+m_c)^2}^{\infty} \frac{d\,s}{\pi}\, \frac{\rho^{(-)}_{abc}(s)}{s-p^2-i\,\epsilon}\,, \tag{162}$$

with the spectral densities

$$\begin{aligned}
\rho^{(\pm)}_{abc}(s) &= \frac{\sqrt{p^2_{ac}}}{8\,\pi\,\sqrt{s}}\, \frac{\log\Big(-\mu^2_{\pm,abc} + \sqrt{p^2_{ac}\,k^2}\,\Big) - \log\Big(-\mu^2_{\pm,abc} - \sqrt{p^2_{ac}\,k^2}\,\Big)}{2\,\sqrt{p^2_{ac}\,k^2}}\,, \\
\mu^2_{\pm,abc} &= \left(\frac{m_c^2 - m_a^2 \mp \bar{p}^2}{2\,\sqrt{s}}\right)^2 - p^2_{ac} - \tfrac{1}{4}\,k^2 - m_b^2\,, \\
k^2 &= \left(\frac{\bar{p}^2}{\sqrt{s}}\right)^2 + s - 2\,\bar{p}^2\,, \qquad \sqrt{s}\; = \sqrt{m_a^2 + p^2_{ac}} + \sqrt{m_c^2 + p^2_{ac}}\,,
\end{aligned} \tag{163}$$

We wrote the logarithm so as to ensure a smooth spectral density. It is important to impose the dispersion-integral representation in terms of the proper variables, i.e. keeping $q^2 = 0$ and $\bar{p}^2 = (p-q)^2$ fixed. This implies that the spectral densities have an implicit dependence on $\bar{p}^2 = p^2 - 2\,p\cdot q$. The alternative representation of the integrals J_{abc} and $\bar{J}_{abc}$ derived through an application of Feynman's parametrization is also useful. We have

$$\begin{aligned}
J_{abc} &= \int \frac{\Theta[z_2 - z_2^2]\,\Theta[z_1 - z_1^2]\,\Theta[z_1 - z_2] dz_1\, dz_2/(16\pi^2)}{(m_c^2 - z_1\,p^2)\,(1-z_1) + z_1\,m_a^2 + 2\,(1-z_1)\,z_2\,(p\cdot q) + z_2\,\mu^2_{ba}}\,, \\
\bar{J}_{abc} &= \int \frac{\Theta[z_2 - z_2^2]\,\Theta[z_1 - z_1^2]\,\Theta[1 - z_1 - z_2]\,dz_1\,dz_2/(16\pi^2)}{(m_c^2 - z_1\,p^2)\,(1-z_1) + z_1\,m_a^2 + 2\,z_1\,z_2\,(p\cdot q)\; + z_2\,\mu^2_{bc}}\,,
\end{aligned} \tag{164}$$

where we used $q^2 = 0$ and $\mu^2_{bc} = m_b^2 - m_c^2$. Depending on the values of the various mass parameters either (162) or (164) may be more economical in a numerical simulation. If $p^2 > (m_a + m_c)^2$ for instance, the representation (162) is advantageous, the integrals being complex. We performed numerical checks using (162) or (164) and verify that the identity $J_{abc} = \bar{J}_{cba}$ is indeed satisfied.

Appendix D

We provide explicit expressions for the contributions of the $\phi\,D_s^*$ and $K^* D^*$ channels to the decay amplitude (85). The latter are linear in the resonance coupling constant g_H introduced in (80). We obtain

$$i\,M^{\alpha\beta,\mu}_{0^+\to\gamma\,1^-} = \frac{e\,g_H}{2\,f^2}\,\Big\{g_T\,E^{\alpha\beta,\mu}_{+,\phi D_s^*}(\bar{p},p) + \tilde{g}_V\,\Big(E^{\alpha\beta,\mu}_{\phi D_s^*}(\bar{p},p) + E^{\alpha\beta,\mu}_{-,\phi D_s^*}(\bar{p},p)\Big)\Big\}$$

$$
\begin{aligned}
&+ \frac{g_H}{4\, f^2\, M_V^2}\left[\tilde e_C - e + \frac{\tilde e_Q}{3}\right]\Big\{ g_T\, \hat E^{\alpha\beta,\mu}_{+,\phi D_s^*}(\bar p, p) \\
&\qquad\qquad + \tilde g_V \left(\hat E^{\alpha\beta,\mu}_{\phi D_s^*}(\bar p, p) + \hat E^{\alpha\beta,\mu}_{-,\phi D_s^*}(\bar p, p)\right)\Big\} \\
&+ \frac{e\, g_H}{2\, f^2}\Big\{ g_T\, E^{\alpha\beta,\mu}_{+,K^* D^*}(\bar p, p) + \tilde g_V \left(E^{\alpha\beta,\mu}_{K^* D^*}(\bar p, p) + E^{\alpha\beta,\mu}_{-,K^* D^*}(\bar p, p)\right)\Big\} \\
&+ \frac{g_H}{2\, f^2\, M_V^2}\left[\tilde e_C - \frac{e}{2} - \frac{\tilde e_Q}{6}\right]\Big\{ g_T\, \hat E^{\alpha\beta,\mu}_{+,K^* D^*}(\bar p, p) \\
&\qquad\qquad + \tilde g_V \left(\hat E^{\alpha\beta,\mu}_{K^* D^*}(\bar p, p) + \hat E^{\alpha\beta,\mu}_{-,K^* D^*}(\bar p, p)\right)\Big\} \\
&- \frac{e\, g_H}{2\, f^2}\Big\{ g_T\, E^{\alpha\beta,\mu}_{-,D^* K^*}(\bar p, p) + \tilde g_V \left(E^{\alpha\beta,\mu}_{D^* K^*}(\bar p, p) + E^{\alpha\beta,\mu}_{+,D^* K^*}(\bar p, p)\right)\Big\} \\
&- \frac{g_H}{2\, f^2\, m_V^2}\Big\{ e_T\, \bar E^{\alpha\beta,\mu}_{-,D^* K^*}(\bar p, p) + \tilde e_V \left(\bar E^{\alpha\beta,\mu}_{D^* K^*}(\bar p, p) + \bar E^{\alpha\beta,\mu}_{+,D^* K^*}(\bar p, p)\right)\Big\} \\
&+ \frac{\tilde e_E\, g_H}{3\, f^2\, m_V^2}\Big\{ \tilde E^{\alpha\beta,\mu}_{D^* K^*}(\bar p, p) + 2\, \tilde E^{\alpha\beta,\mu}_{D_s^* \phi}(\bar p, p)\Big\} \\

$$

The evaluation of the decay constant $d_{0^+\to\gamma 1^-}$ defined in (87) is done by contracting the gauge-invariant tensors (88, 90, 91, 93) and (166) with the anti-symmetric tensor

$$
P^{(1-)}_{\alpha\beta,\mu} = -\frac{1}{2} \left(\left\{ g_{\mu\alpha} - \frac{p^\mu\, q^\alpha}{p \cdot q} \right\} \bar p_\beta - \left\{ g_{\mu\beta} - \frac{p^\mu\, q^\beta}{p \cdot q} \right\} \bar p_\alpha \right)\,. \qquad (167)
$$

We derive the required contractions in terms of the master loop integrals $I_{ab}, \bar I_{ab}, J_{abc}$ and $\bar J_{abc}$ introduced in (159). Following the arguments of Section 3.3, reduced tadpole integrals are dropped systematically. Using the notation $p^2 = M_i^2$ and $(p-q)^2 = M_f^2$, we have

$$
\begin{aligned}
&8\,(p\cdot q)\, M_i^2\, P^{(1-)}_{\alpha\beta,\mu}\, A^{\alpha\beta,\mu}_{ab} = \Big[M_i^6 - \left(m_a^2 - m_b^2 + 2\, M_f^2 \right) M_i^4 \\
&\qquad - M_f^2 \left(2\, m_a^2 - 2\, m_b^2 + M_f^2 \right) M_i^2 + \left(m_a^2 - m_b^2 \right) M_f^4 \Big]\, I_{ab}
\end{aligned}
$$

$$+\,2\,M_f^2\Big(m_a^2-m_b^2+M_f^2\Big)\,M_i^2\,\bar{I}_{ab}+4\,m_a^2\,M_f^2\,M_i^2\Big(M_i^2-M_f^2\Big)\,J_{aab}\,,$$

Appendix E

We provide the contributions of the $\phi\, D_s^*$ and $K^* D^*$ channels to the decay amplitude $M^{\mu,\alpha\beta}_{1^+\to\gamma 0^-}$ introduced in (96). All terms are linear in the coupling constant $\hat{g}_H$ (see (80)). We obtain

$$
\begin{aligned}
M^{\mu,\alpha\beta}_{1^+\to\gamma 0^-} &= \frac{e\, \tilde{g}_T\, \hat{g}_H}{8\, f^2} \Big\{ F^{\mu,\alpha\beta}_{-,\phi D_s^*}(\bar{p},p) + E^{\mu,\alpha\beta}_{+,D^*K^*}(\bar{p},p) + F^{\mu,\alpha\beta}_{-,K^*D^*}(\bar{p},p) \Big\} \\
&\quad + \frac{e\, g_E\, \hat{g}_H}{8\, f^2} \Big\{ F^{\mu,\alpha\beta}_{+,\phi D_s^*}(\bar{p},p) + E^{\mu,\alpha\beta}_{-,D^*K^*}(\bar{p},p) + F^{\mu,\alpha\beta}_{+,K^*D^*}(\bar{p},p) \Big\} \\
&\quad + \frac{\hat{g}_H}{16\, f^2\, M_V^2} \Big[\tilde{e}_C - e + \frac{\tilde{e}_Q}{3} \Big] \Big\{ g_E\, \hat{F}^{\mu,\alpha\beta}_{+,\phi\, D_s^*}(\bar{p},p) + \tilde{g}_T\, \hat{F}^{\mu,\alpha\beta}_{-,\phi\, D_s^*}(\bar{p},p) \Big\}
\end{aligned}
$$

$$

\tag{170}
$$

The decay constant $d_{1^+ \to \gamma 0^-}$ defined in (97) is computed by contracting the gauge-invariant tensors (98- 101, 104) and (170) with the antisymmetric tensor

$$
P^{(0-)}_{\mu,\alpha\beta} = -\frac{1}{2} \left(\left\{ g_{\mu\alpha} - \frac{p^{\mu}\, q^{\alpha}}{p\cdot q} \right\} p_{\beta} - \left\{ g_{\mu\beta} - \frac{p^{\mu}\, q^{\beta}}{p\cdot q} \right\} p_{\alpha} \right). \tag{171}
$$

We provide the results in terms of the master loop integrals $I_{ab}, \bar{I}_{ab}, J_{abc}$ and $\bar{J}_{abc}$ introduced in (159). According to the arguments of Section 3.3 reduced tadpole integrals are dropped. Using $p^2 = M_i^2$ and $(p-q)^2 = M_f^2$, we derive

$$
\begin{aligned}
16\,(p\cdot q)\, M_f^2\, P^{(0-)}_{\mu,\alpha\beta}\, A^{\mu,\alpha\beta}_{ab} = & \; 2\, M_f^2 \Big[M_i^6 - \left(m_a^2 - m_b^2\right)^2 M_i^2 \\

[47] In Eq. (8) of [13] there are two misprints. In the expression for V_{0+} ,the sign of the s-channel contribution has to be reversed. In the expression for V_{1+}, the r.h.s. has to be multiplied by a factor 3/2. As a consequence the numerical values given in Table 3 change slightly. The conclusions of the work are not affected.
